It pleaseth *Gesner* to name the first *Chamæmespilum*, whom almost all since have followed; and called so in like manner, onely *Lugdunensis* calleth it *Epimelis*, and maketh it the *Mespilus* of *Dioscorides*, which he saith some called *Epimelis*, and some *Setainum*, when as himselfe saith in his Chapter of Medlars, that *Dioscorides* his *Mespilus Setania*; is our common Medlar, whose fruite as well as tree is farre greater then of this. The second is the *Epimelis of Galen*, whereof he maketh mention *lib. 6. simpl. medic.* and differeth from the Medlar so called; whereof he speaketh in another place; for he saith that the fruite hereof is sowre, and hurtfull to the stomacke; and that the Country people of *Italy* did call it *Vnedo*, (which is probable they did so, because the blossomes are very like those of the *Arbutus* which is also called *Vnedo*) *Lugdunensis* calleth it *Epimelis altera*; but is not *Clusius* his third *Vitis Idæa*, as he thinketh, which hath blacke berries, but this hath red as he describeth it, and therefore therein was deceived, yet thinketh it to be the *Cotonaster* of *Gesner*, which *Clusius* contradicteth. The third is indeede the *Cotonaster* of *Gesner*, which *Clusius* also mentioneth in his history of plants, with his *Chamæmespilus*, and *Vitis Idæa*. *Bauhinus* maketh a doubt whether it be not the *Agriomelea* of *Bellonius*. *Bauhinus* seemeth to make two severall plants thereof, as may be seene in his *Pinax*. These plants have gotten sundry *Germane* names among the *Alpish* inhabitants and others, as by these divers names in Latine derived, for the *Germane* may be easily understood, and because we wanted names to call them by, I have given it them as neere as I can, either from the Latine or their proper effects, and thus much may suffice untill we further be informed of them.

*The Vertues.*

There can be little said of any of these plants, seeing so little hath beene said by those moderne Authours, that first wrote of them: for some of them being dry berries, are wholly neglected, and the other that have some better rellish or sweete taste, are onely eaten by the Mountainers and their children, and not applyed as medicinable for any griefe.

---

## CHAP. XXVI.

### *Acer.* The Maple tree.

THere are onely foure sorts of Maple trees knowne to us, that I am to shew you, but *Bauhinus* doth distinguish them into foure thus, *Sphendamnus* is that Maple that is white and full of veines, *Zygia* is yellow and crispt, *Clinotrochon* is yellow and not crispt, *Glinon* is white with few veines, but wee must give them you by other termes.

1. *Acer majus latifolium Sycomorus dictum.* The great broad leafed Maple or Sicomore tree.

The great Maple (which hath beene with many falsely called the Sycomore tree) groweth quickly to be a great

1. *Acer majus latifolium Sycomorus falso dictum.*
The great broad leafed Maple or Sycomore tree.

2,3. *Acer minus & montanum.*
Our common wood Maple and the mountaine kinde.

and a tall tree, spreading many faire branches, which make a goodly shadow, covered with a reasonable smooth barke, having many very faire large leaves thereon, set upon reddish footestalkes, cut somewhat deepely into five somewhat long parts or divisions, all dented about the edges, greene above and grayish underneath, the flowers are of a whitish yellow greene colour, standing on a long stalke, with some few threds within them, each flower yeelding two winged huskes, parted at the stalke, which are thinne skinnes at the ends, and bunched out, where the seede lyeth within, and are very like unto the common or wood Maple, but much larger, and many more standing together: the wood is whitish and smooth, but not so white, smooth, and close, as the wood kinde is.

4. *Acer Creticum trifolium.*
The three leafed Maple tree.

2. *Acer minus sive vulgare.*

Our common or wood Maple tree.

The common Maple tree groweth lower & slower then the former, somtimes in hedges, no higher then those other hedge bushes, or els much highe r covered with a more rugged barke, spreading neither so far nor such great branches, the leaves are much smaller, thinner and not so deepely cut in, but yet divided into five parts, and somewhat broad, at the setting on of the stalke, of a deepe and shining green colour on the upperside, and paler underneath: the flowers and seede are very like the former, but fewer set on the stalkes, and lesser also in bulke or bignesse; the wood hereof is very white, very smooth, and very close grained.

3. *Acer montanum.*

The mountaine Maple tree.

This Maple differeth little from the last, that groweth well and great, differing chiefely in the leafe which is not flat next unto the stalke, and is somewhat deepelier cut into more divisions.

4. *Acer Creticum trifolium.*

The three leafed Maple of *Candy*.

This Maple groweth to be a tree of a meane sise, spreading branches reasonable well, the barke whereof is of a darke reddish colour, having broad greene leaves full of veines, divided into three parts, standing equally distant one from another, with a long slender footestalke under them, the flowers stand onely a couple together on the stalke, as the seede that followeth doth also, winged somewhat like the last but smaller.

*The Place and Time.*

The first is no where found wilde or naturall in our Land that I can learne, but onely planted in Orchards or walkes for the shadowes sake, but groweth in sundry places in *Germany, &c.* The second and third are found both on high and low grounds, in Woods, and Groves, Parkes, Chases, and the like through most Countries of this Kingdome, the one in the moister grounds, where the wood will be looser, and the other in the dryer grounds, firmer and closer; but the last is also a stranger to us, growing about *Mompelier* and *Candy*, they all flower about the middle of *Aprill*, and the seed is ripe in the end of *September*.

*The Names.*

It is called in Greeke σφενδάμνος & *Sphendamnus*, in Latine *Acer*. The first is that which *Clusius* calleth *latifolium*, because it hath the greatest and broadest leaves of any, and therefore *Tragus* calleth it *Platanus*, thinking as divers did, that it was the true *Platanus*, and therefore the *French* did call it *Plane*, before the true one was discovered and knowne. *Ruellius* and after him many others called it *Sycomorus* the Sycomore tree, which in divers Countries doth still continue, and with us also being called usually the Sycomore tree: but by this name of *Sycomorus* the Sycomore tree, divers Writers have called divers trees, as first the true Sycomore or Mulberry Figge, called of divers *Ficus Pharaonis*, *Ficus Ægyptia*, *Morus Ægyptia*, and *Ficus Cypria*. *Matthiolus* and others say that the *Italians* call the *Azadarach* by the name of *Sycomorus*. And *Petrus Crescentius*, calleth the *Virga sanguinea*, by the name of *Sycomorus*. And lastly *Ruellius* and others say that this *Acer latifolium*, is called *Sycomorus*, yet *Clusius* saith that the *French* call the lesser or wood sort so. The second is that which is most frequent in our Land, and called *Acer tenuifolia*, by *Cordus* in *histor. Acer minor* by *Dodonæus*, *Clusius*, and *Camerarius*, *Opio* by the *Romanes*, *Opulus* by *Gesner in hortis*, and *Cordus*, and *Opulus campestris* by *Lugdunensis*, who also taketh it to be *Carpinus*, but not rightly. The third is the *Aceris altera species, quæ fortè Zygia Theophrasti* of *Lobel*, by *Bellonius Acer montanum, flavum & crispum*, and *Asphendamnos* by the Country men of *Candy*, by *Lugdunensis Opulus montanus*, and can be no other then the *Zygia* of *Theophrastus*, which *Gaza* calleth *Carpinus*, which differeth much from the *Ostrys*, which some as is before said call *Carpinus*. And the last his *Glinon*, which hee rendereth *Gallicum*. The *Italians* call it *Pie doca*, and *Platano acquatico*, the *French Erable*, the *Germanes Masshoider* the common sort, and *Ahorne* the greatest, the *Dutch Luytenhout*, and we in *English* Maple, and some, but as falsly as the *French* or any other, the Plane tree.

*The Vertues.*

Neither *Dioscorides* nor *Galen*, in his censure of simples, make any mention of this tree, yet *lib. 8. med. part. cap. 8.* in the medicines for the Liver, written by *Asclepias*, he appointeth a dramme of the roote to be beaten to pouther, and given in water, but *Cornarius* doubteth that the word is mistaken, because none of the Greeke Writers have made any mention thereof, or that it should be used in any disease. And none but *Pliny* hath recorded any of these Maples, but saith that the roote of the Maple being bruised, is applyed with very great effect unto those that have obstructions, or any other paines of the Liver, or Spleene, which *Serenus* delivereth in these Verses following:

Si

*Si latus immeritum morbo tentatur acuto,*
*Accensum tinges lapidem stridentibus undis,*
*Hinc bibis: aut Aceris radicem tundis, & una*
*Cum vino capis, hoc præsens medicamen habetur.*

*Thy harmelesse side, if sharpe disease invade,*
*In hissing water quench an heated stone,*
*This drinke: Or Maple roote in pouther made*
*Take oft in Wine, a present medicine knowne.*

It is used in many joyners works, especially the finest wrought grained wood, which *Pliny* peradventure meant *lib.16.c.16.* by that which he there calieth *Bruscus*, and *Molluscus*, the more excellent both of them as he saith, is *tuber Aceris*, the knotty part of the tree, or of the roote thereof, which is held to be fuller of diversified veines therein: either of which saith *Pliny*, if they were large enough to make a table, would excell the Cedar, as some take it, but others thinke it should be *Citrus* the Citron.

## CHAP. XXVII.

1. *Platanus orientalis verus.* The true Planetree of the East Countries.

BEcause in the last Chapter it is shewed that the *French* and others were utterly mistaken in calling the Maple the Plane tree: I thought it meetest to shew you which is the true kinde next thereunto, and to joyne thereunto another sort, brought by Mr. *Tradescant*, out of *Virginia*. It riseth up to be a very great tree in time, spreading very largely, the barke whereof is rugged, the leaves are very large, cut into five divisions, and each of them deepely gashed on the edges, greene above and whitish underneath, hanging by a slender reddish stalke, the flowers are of a pale white colour, many set together on a long stalke, after which follow sundry round rough bals of the bignesse of Wallnuts, made as it were a bur, but not sticking, wherein lye small seede, the wood is firme, hard, and yellowish browne.

2. *Platanus Occidentalis aut Virginensis.* The Plane tree of the West parts or *Virginia*.

This Plane tree likewise groweth great, and spreadeth fairely, whose leaves being broad and large, have not so deepe divisions in them, and the pills or burres are, although somewhat rough with the compleat roundnesse, not so sharpe as the former, which being set hereby is utterly spoyled in the cutting, they grow also many hanging downe from the ends of the branches, as in the others.

1. *Platanus Orientalis verus.*
The true Plane tree of the East Country.

2. *Platanus Occidentalis aut Virginensis.*
The Plane tree of the West parts or Virginia.

*The Place* and *Time.*

The former groweth not naturally in any Country of *Europe*, but in *Asia*, *Syria* *Egypt*, and *Africa* many, and they are planted also by the way sides, and in market places, for the shadowes sake onely: it is found with very few in our Christian world, and those onely great lovers of rarities, being very tender, not enduring without extraordinary care and keeping, the cold of our climates, the other is but lately brought from *Virginia* by M. *Tradescant.*

*The Names.*

It is called πλάτανος in Greeke, and *Platanus* in Latine, *a latè diffusis ramis nomen sortita est*: and by this name all Authours have called it that have written of it. The *Arabians* call it *Dulb*, the *Italians* *Platano*, the *French* *Platane*, that it may differre from the *Plasne*, whereby as is said they call the Maple, the *Germanes* know it not, and therefore they and the *Dutch* have no peculier name, but as they take it from the *French* *Plane*, even as we doe also, calling it the Plane tree: *Dioscorides* calleth the fruite or burres σφαιρία, and *Pliny* *Pilulæ*. The *Virginian* being so like the other can have no other name.

*The Vertues.*

*Galen* saith that the Plane is of a moist and cold nature, but not farre from a temperate, and therefore the green leaves bruised and laid on inflammations and hot swellings doe helpe them, but the barke and the burres are more drying, which being boyled in vinegar, is good to gargle the mouth for the paine of the teeth: the burres also fryed with fat is good against burnings, the burnt barke mixed with water doth clense the skin of any scurfe, lepry, or other deformities of the skin, and doth dry up much also, old moist and running ulcers, bringing them to cicatrising: there is saith *Galen* and *Dioscorides*, a kinde of dust upon the leaves, which every one must be carefull to avoid, that it fall not into their eyes or eares, least it put them to much paine, the burres drunke in wine, resisteth the venome of the Scorpion, and other venemous creatures, the young tender leaves boyled in wine, and the eyes bathed therewith that have either rednesse or rheumes falne into them helpeth them.

## CHAP. XXVIII.

### *Buxus.* The Boxe tree.

THe Boxe tree, hath two or three diversities observed therein, which shall be shewed here, and with them another, which divers doe referre hereunto.

1. *Buxus arbor vulgaris.* Our common Boxe tree.

The Boxe tree groweth slowly, and seldome groweth to any great body, or any great height, but when it is suffered, after a long time riseth unto twise a mans height, and of the bignesse of a mans thigh, with a grayish barke, but in many places very low, spread reasonable well, with branches, whereon are set many thicke small, somewhat long and round pointed leaves, abiding alwayes greene, larger, thicker, and greener then any ordinary Mirtle leaves, greater or lesser, as the bushes be in greatnesse, at the foote of the leaves come forth small greenish flowers, which turne into whitish round berries, with foure points at the toppes, with reddish seede within them: the wood is very solid close, of a whitish yellow colour, and so heavy that it sinketh being put into water.

2. *Buxus auratus.* Guilded Boxe.

This guilded Boxe groweth in like manner as the former, in some places taller and greater then in others, the leaves are altogether like it, but that most of the upper leaves in the Summer time will have a yellow list or guard about the edges, and in nothing else differing from the other.

3. *Chamæbuxus minor.* Small low Boxe.

This small Boxe groweth never high or great, and although neglected or suffered yet still it hath many slender twigs rising from the roote, and every branch apt to take roote, whereby it may quickely be propagated and encreased, the leaves are much smaller and finer then in the former, and of a deeper greene colour, which never bore flower or seede that I could observe or learne.

4. *Pseudo chamæbuxus.* The bastard low Boxe.

This small low plant lyest most on the ground, with the slender rushlike greenē branches, rooting as it spreadeth, and not rising a foote high having divers thicke hard leaves set theron without order, somewhat like unto Boxe leaves, or rather Mirtle leaves, being for the most part pointed at the ends, ever abiding greene: at the ends of the branches among the leaves come forth foure or five flowers of the fashion of Pease or Broom blossomes, the uppermost part whereof is whitish, and yellowish in the middle, but purplish lower, and in some purple above, and yellow below, after which come small flat cods like unto the broad *Thlaspi*, containing within them blackish gray round seede like Vetches: the roote spreadeth tough long branches in the ground, and abideth long.

*The Place* and *Time.*

The first is found with us in many woods, and wood grounds among other sorts of trees, it is also planted in divers Orchards, or house backe sides, where it never groweth high, but serveth as a bush to dry Linnen on, &c. The second hath beene likewise found in sundry places of this land, but onely neere those that have it. The third groweth also in gardens being planted either as a border to keepe up the beds, or as a hedge likewise to dry cloths on. The last *Clusius* found in sundry places of *Austria*, and *Hungaria*, and *Cordus* on the hils in *Bavaria*, &c.

*The Names.*

Boxe is called πύξος in Greeke διὰ τὸ πυκνὸν τοῦ ξύλου *adensitate ligni dicitur*, and *Buxus* in Latine, and therefrom came *pixides* the small vessels or boxes to hold and containe things in them. *Theophrastus* and *Dioscoridess* have but one sort, but *Pliny* hath three, the first he calleth *Gallicum*, because it was made to grow into spires or pillars, unto a great height. The second *Oleastrum*, (but as *Dalechampius* on *Pliny* noteth, there is an errour in the mistaking of the word, in some Greeke copy that he followed, and for ἀγριόλον εἶναι, *secundum omnino agreste esse*, he tooke it to be ἀγριέλαιον εἶναι, *Oleastrum esse*) is wholly wild, and not profitable for any thing as the first kind is, being of a most loathsome sent, not fit to set against the house sides, as the third is: Another errour *Pliny* hath, that he saith the head of seede is called *Cratægus*, which he doth confound out of *Theophrastus* that speaketh of *Cratægus* next after *Buxus*, *lib.* 3. *c.* 15. and a third errour herein is, that he saith the Boxe beareth *Viscum* on the

1. *Buxus arbor vulgaris.*
Our common Boxe tree.

4. *Pseudo chamæbuxus.*
The bastard low Boxe tree.

the North side, and *Hyphear* on the South, which *Theophrastus* saith of the *Ilex* to doe so. The first is generally called *Buxus & arbor*, or *arborescens* by all. The second hath not beene mentioned by any Writer before me. The third is called *Chamapyxos* by *Tragus*, and *Tabermontanus*, and *Buxus humilis* by *Dodonæus*. The last is the *Anonymos flore Colutæ* of *Clusius*, the *Anonymos Pervincæ folio* of *Camerarius in horto*: and *Rhus Myrtifolius Plinij Gesneri* also, *Gesner* in *Collatione stirpium* calleth it *Chamæbuxus*, and *Besler* that set out the great *hortus Eystensis*, *Pseudochamæbuxus* as I doe. *Thalius* calleth that small plant *Myrtus tenuifolius*, that *Cordus* calleth in *Observationum sylva*, *Fruticulus exiguus folijs myrtinis*, which is this very plant. Box is called *Bosso* by the *Italians*, and *Box* by the *Spaniards*, *Boys* by the *French*, *Buxbaum* by the *Germanes*, and *Palmboom* by the *Dutch*.

*The Vertues.*

The leaves of Box are hot and dry, and astringent withall, as the taste declareth, and therefore assuredly doth dry and binde, yet is it not much used in Physicke by any now adayes that I know, although many doe trumpet out the praise of it to be good for fluxes, and the *French* disease, as much as *Guajacum*. *Fernelius* onely doth number the leaves hereof among those things that doe purge, but the practise thereof is worne out of use, yet I remember that Doctor *Smith*, that was one of Queene *Elizabeths* Physitions, appointed the decoction of an ounce of the leaves of Boxe for a purging medicine, to be boyled in whey, and a dramme of the pouther in broth. But *Matthiolus* contesteth against such as tooke it, and the *Guajacum* to be both one: the leaves and the dust of the wood boyled in lye, will make haires of an Aborne (or *Abraham*) colour, the dwarfe Boxe is fit as is said to border the beds of a Garden, &c. and either they or the leaves of the other dryed and given to horses, cureth them of the Bots, or Wormes: the wood is used for many small workes among the Turners, and the diversified boxe that hath crooked veines therein, serveth for inlaying to Joyners: there is no use knowne of the last as yet.

One medicine that I learned of a friend, who had tryed it effectuall, I will here set downe unto you, to cure the biting of a mad dogge, is to take the leaves and rootes of Cowslips, of the leaves of Boxe and Penny-royall, of each a like quantity, shred them small and put them into hot broth, and let it be so taken three dayes together, and apply the herbe, &c. to the bitten place, with sope and hogges suet melted together.

---

## CHAP. XXIX.

### *Salix.* The Willow.

THe Willowes are to be divided into sundry parts, for some grow high, some low, some with broad leaves, some with narrow and long, and that both high and low, some also onely growing in the waters, others delighting to grow by water sides, and ditches, yet will also grow on the land. I will therefore distribute them into foure peculiar sorts or orders, that is to say into those that grow high

1. *Salix arborea angustifolia alba vulgaris.* The ordinary great white Willow tree.

3. *Salix rosea.* The Rose Willow.

and beare narrow leaves, into those that grow high, and beare broad leaves, into the lower sort with broad leaves, and into the lower with narrow leaves, and so I shall comprehend the whole number of them; and yet I must seperate the *Spyræa* of *Clusius* and the *Vitex* or *Agnus castus* into two chapters by themselves.

1. *Salix arborea angustifolia alba vulgaris.*
The ordinary great white Willow tree.

Our ordinary white Willow groweth quickely to be a great and tall tree, if it be not lopped as it is usuall in most places, with a smooth white barke on the body, and bigger branches, the younger sprigges, being somewhat greene with the whiteneſſe, the leaves are long and narrow, pale greene on the upper side, and of a shining silver white colour underneath, without any dent on the edges, the flowers come forth before the leaves appeare, and are small long and round, yellow mossie heads, smelling sweete for the most part, divers standing one above another, on a long stalke, which in time turne unto downe, that is blowne away with the winde, and the seede with it if it have any: the wood is soft and white, and with the branches hereof cut into long sticks are made stakes for hedges, or to uphold Vines, &c.

2. *Salix angustifolia purpurea seu nigra.*
The ordinary blacke Willow.

The blacke Willow differeth from the former white not growing so great or high, and that the barke is more rough and of a darke reddish colour, the branches lithy and easie to bend, as whereof hopes are made to binde caskes, the leaves likewise are narrower and blacker, and wood not so white.

5. *Salix Viminalis nigra.* The blacke Withye.

3. *Salix Rosea.* The Rose Willow.

The Willow that beareth a tuft of small greenish white leaves, on the reddish branches, set in order together almost like a Rose, is in growth like unto the last; the barke as rough and darke; the leaves not so long nor the branches fully so lithye and pliant, yet reasonably.

4. *Salix fragilis.* The hard blacke Willow.

This differeth from the second, in that the branches are hard and blacke, strong, and not pliant as the former, &c.

5. *Salix viminalis nigra.* The blacke Withy.

This Withy hath more slender branches, and more fit to be wound, of a darke red colour: the leaves are long and narrow, dented about the edges, of a darke greene, and a little white underneath, having two small round leaves, at the setting on of every the long leaves, which sheweth the kinde thereof.

6. *Salix Gallica nigra.* The *French* blacke Withy,

This differeth from the last in this, that the twigges are more yellowish browne, the leaves lesse dented and hath no small round leaves at the bottome of the longer.

*The Place* and *Time.*

Many of these sorts are found in our owne land in low grounds, neere water courses and ditches, and the Rose Willow in sundry places of *Essex*, and *Cambridge* shire: the blossomes come forth before any leaves appeare, and are in their fullest greatnesse usually before *Easter*, divers gathering them to decke up their houses on Palme sunday.

*The Names.*

It is called in Greeke ἰτέα, παρὰ τὸ ἴεσθαι, *quod cito in altum excrescat*, and *Salix a saliendo* in Latine, because it groweth with that speed that it seemeth to leape. The first is common both with us and with other nations, and is that which *Theophrastus* and *Pliny* call *Salix alba*, and *Salix perticalis* by *Matthiolus*, *Cordus*, *Lugdunensis* and others, because the branches thereof being strong are used as stakes to hold up any thing, or to be bound thereunto. The second is taken to be the true *Salix Amerina nigra & rubens* of *Pliny*, and of *Columella Salix Amerina & Sabina*, which *Matthiolus* calleth *Græca*, and *Dodonæus Gallica*, and by *Thalius Sabina*, and *Amerina*. The third is not mentioned by any forraigne Authour that I know of, *Gerard* having given the first knowledge thereof to the world. The fourth is called by *Bauhinus Salix fragilis*, as it is in the Title. The fift is called by *Lugdunensis Salix* μελανόφλοιος, *i.e. cortice nigro* of *Theophrastus*, and the *purpurea* of *Pliny*. The last is the first *Salix* of *Tragus*, the *Salix Gallica* of *Cordus* on *Dioscorides*, and by *Lugdunensis Salix Phœnicea*. The *Arabians* call the Willow *Bulef Bhulles*, and *Saffaff* also, and *Chalif*, which names *Alpinus* and *Rauwolfius* give to their particular kindes, the *Italians Salice*, the *Spaniards Salce*, and *Salgueiro*, the *French Saulx*, and *Saule*, the *Germanes Weiden* and *Felbinger*; the *Dutch Milgheboom.*

*The Vertues.*

The Vertues of all the sorts of these Willowes, as of the rest are set downe together at the latter end of them, except such as are mentioned in particular.

## CHAP. XXX.

*Salix arborea latifolia.* The Sallow tree.

OF this kinde there are divers sorts that plainely differre both from the former and among themselves.

1. *Salix latifolia rotunda.* The round leafed Sallow.

This Sallow groweth to a reasonable greatnesse with a grayish white rugged barke outermost, and another redder inward, the outermost being pliant, and strong, fit to binde things withall: the leaves hereof are broad and almost round, endented about the edges, darke greene above and gray underneath with two small round leaves joyned to the foote of them: the flowers or catkins are not such whole heads or tufts as the former kinde, but consist of many small heads, thicke set together, which are blowne away with the blackish seede in them as the others are: the wood hereof is more loose and spongy then the other, and may by beating the head be writhed round or downeward, as is seene at the Christmas time in many Noble and Gentlemens houses set at their gates by their Porters.

2. *Salix latifolia oblongior.* The longer leafed Sallow.

This other differeth from the former onely in the leaves, which are not so round, but broad and long withall, dented about the edges, and in all things else alike: on the leaves of both these sorts are found sometimes certaine bladders or blisters, and upon the branches little rough balles.

3. *Salix latifolia minor.* The lesser broad Willow.

There is another sort hereof that groweth not so high as the former, the leaves being of a meane sise, betweene them two that is not so round nor so long, but of a darker greene colour, and gray underneath like unto them.

4. *Salix subrotundo argenteo folio.* The silver leafed Sallow.

This silver leafed Sallow groweth low like the last, having a brownish barke to cover the body, but especially the branches, the leaves are more long then broad, and shining silver-like underneath, somewhat lesser then the last, the leaves and the barke being the chiefest differences in this from the last.

*The Place* and *Time.*

These sorts although they are sometimes found by waters sides, yet are they also found in the moister grounds, not neere crookes or ditches, and in the upland grounds as well: their time of flowring is with the former.

*The Names.*

This kinde is called *Salix arborea latifolia* to distinguish it from all the other kindes: the two first sorts are mentioned by *Tragus*, as his fourth kinde, and called *Latifolia* or *platyphyllos* by *Clusius*, *Camerarius*, *Thalius*, *Gesner*, *Lobel*, and *Lugdunensis*, which *Tabermontanus* and *Gerard* call *Salix caprea rotundifolia*; and thought to be *Eleagnus* by some, and called *Salix latifolia aquatica* by others. The third is mentioned by *Thalius* onely, and

1. *Salix latifolia rotunda.* The round leafed Sallow.

2. *Salix latifolia oblongior.* The long leafed Sallow.

and by *Bauhinus* from him. The last by *Bauhinus* onely, who calleth it *Salix subrotundo argenteo folio*, as it is in the title.

## CHAP. XXXI.

*Salix pumila latifolia.* The low broad leafed Willow.

THere are likewise three or foure sorts of this low kinde to shew you, which are as followeth.

1. *Salix humilis latifolia erecta.* The upright low broad Willow.

The branches of this low Willow are short, not above a cubit long and straked, or as it were crested all along: the leaves are somewhat long with the roundnesse and pointed at the ends, a little wrinckled above, and soft and woolly underneath: this creepeth not as the next, which distinguisheth it.

2. *Salix latifolia repens.* Creeping broad leafed Willow.

The stalkes with the sundry branches of this low Willow, having a rugged barke, doe for the most part spread on the ground, and take roote againe as they lie, the leaves are small, yet somewhat broad and long, pointed at the ends, greene above and gray underneath and shining, the catkins hereof are thicker and shorter then in any other of these lower sorts, the rootes hereof spread much in the ground.

3. *Salix latifolia Alpina repens.* Creeping mountaine broad leafed Willow.

This other sort differeth little from the last, having a little smoother bark, a few rounder leaves, and smaller catkins, which abide untill *August*, and then shew their small blacke seede within them, and great rootes much spread.

4. *Salix saxatilis minima.* The least red or stone Willow.

The stocke hereof is thicke at the bottome, but short, sending forth two or three slender short branches, lying on the ground, having long and somewhat round darke greene leaves thereon, with many veines therein, at the end whereof standeth a small round head made of many small graines as it were set together, which when they are ripe open themselves and sheweth forth a short soft white downe, out of a three square huske, which is carryed away with the winde.

5. *Salix pumila abortiva.* The least Willow without fruite.

This Willow groweth not much higher then ones hand with such small round leaves thereon, white on both sides, that they exceede not the bignesse of a penny, standing close together, without either flower or seed, that it can scarse be taken for a Willow.

6. *Salix Ægyptiaca & Syriaca.* The *Egiptian* Willow or of *Syria*.

This Willow that groweth familiarly both in *Egipt* and *Syria*, is neerer a shrub then a tree, spreading into many slender flexible and yellowish branches and stemmes also from the roote, whereon are set faire broad and large leaves

2,3. *Salix humilis latifolia & Alpina repens.*
The Creeping broad leafed and mountaine Willow.

6. *Salix Ægyptiaca & Syriaca.*
The Egyptian Willow or of Syria.

leaves on both sides, yet but one at a place, usually, especially on the younger stemmes and branches, but grow smaller on the elder, with some lesser with them also, greene on the upper side, and grayish underneath: at every joynt with the leafe usually commeth forth a whitish ball or tuft, of a soft flocky substance, which by time is dispersed into the aire, without bearing any seede for ought that hath been observed, yet may be in that flocky matter, as is usuall in many other plants that beare flocky heads: but because the flowers are very plentifull, and sweete withall, the Natives distill a water from them, whereof they make a great account, calling it *Machaleb*, using it as an especiall helpe for all sorts of agues, but especially in pestilentiall and putride feavers, as also the infusion or decoction of the flowers and for paines in the head and faintings of the heart, and the comforting and strengthening thereof.

7. *Salix Arabica humilis folijs Atriplicis.*
The *Arabian* dwarfe Willow.

This *Arabian* likewise groweth low, with many pale yellowish branches, but thicker, more solid and strong then the last, beset on all sides with leaves, that are of an handbreadth long, and two inches broad, somewhat jagged on the edges like unto a wild Arrache, what flowers or fruite it bore, was not observed, but of the coles of this sort of Willow, they make their best Gunpouther.

*The Place* and *Time.*

Some of these sorts are found in many places of this Land, as upon *Hampstead* Heath, *Rumney* Marshes and the like, although *Clusius*, *Lugdunensis*, and *Bauhinus*, have recorded them to grow in *Germany*, *Hungary*, and *Savoy*, *&c.* The two last according to their titles.

7. *Salix Arabica humilis folijs Atriplicis.* The Arabian dwarfe willow.

The

*The Names.*

*Bauhinus* calleth the first by the name in the title, as he doth the fourth also. The second and third *Clusius* calleth *Salix pumila latifolia*, the third here being his first, and his second, the second here. The fifth *Lugdunensis* calleth *abortiva*, as it is in the title. The sixt is remembred by *Alpinus* among his *Egiptian* plants, calling it *Calaf sive Ban*, and *Vestingius* saith the *Egiptians* and *Syrians* call it *Caleb* also, *Rauwolfius* saith the *Syrians* called it *Saffaf*. The last *Rauwolfius*, also saith is called *Garb* by the *Arabians*, and *Garrab* by the Moores.

## CHAP. XXXII.

*Salix pumila angustifolia.* Low narrow leafed Willowes.

HEreof there are divers kindes which grow diversly some in more wet places then others, and first I must speake of the *Osier*, because although it grow with longer twigges or roddes, then many of the rest, yet it beareth narrow long leaves.

1. *Salix aquatica humilis.* The Osier.

The Osier hath a stumpe or stocke of a tree, as bigge as ones arme at the most, and not above a foote high, put with an head as bigge as a childes head, being kept thus low of purpose, because the shootes or wands that rise out of it, are cut every yeare for use, the barke whereof in some is yellowish or whitish, in others brownish, the leaves are long and narrow, yet broader then any of the rest for the most part that follow, dented about the edges, darke greene on the upper side, and whitish underneath: this hath not beene observed to beare any flowers, because all the shootes are yearely lopped off close to the head, but the rods thrust into the ground will spring to be young trees, to be dressed in like manner, and so will any branch of the former greater sorts.

2. *Salix pumila angustifolia recta.* The straight dwarfe Willow with narrow leaves.

The stemmes of this Willow are slender yet upright, not above a foote long, covered with a yellowish barke: the leaves are narrow and long like unto those of Line or Flaxe, greene above and gray below, the young ones being wholly gray and hoary: the bloomings or catkins are soft and yellow, like the greater kindes, and come forth before the leaves, and passe into downe being ripe, that is blowne away with the winde, the roote is blacke of a fingers bignesse with fibers thereat, growing a slope.

3. *Salix humilis angustifolia repens.* Creeping low Willow with narrow leaves.

The branches of this low Willow, grow to be a foote or more long, but slender and leaning, and lying upon the ground, where it will shoote forth rootes againe, set with shorter and narrow leaves, divers comming forth together, greene above and gray below, in other things not unlike the former.

1. *Salix aquatica humilis.*
The Osier.

2. *Salix pumila angustifolia recta.*
The straight dwarfe Willow with narrow leaves.

4. Salix

3. *Salix humilis angustifolia repens.*
Creeping low Willow with narrow leaves.

4. *Salix oblongo incano folio.*
The blacke low Willow.

4. *Salix oblongo incano acuto folio.*
The blacke low Willow.

The stemme hereof is covered with a darke red barke, parted into sundry short branches with narrow long and sharpe pointed darke greene leaves upon them, and hoary underneath, the rest agreeth with the former.

5. *Salix Helice Theophrasti.*
*Hungarian* low Willow.

The branches of this Willow are very slender and pliant, though the body bee somewhat great, covered with a pale yellowish barke, the leaves grow by couples, being long narrow and sharpe pointed, greene with a certaine hoarinesse above and gray underneath, with some small leaves at the bottomes of them, and with small reddish bals or blisters sometimes on them also: the flowers, &c. agree with the former, but this is proper hereunto to have scaly heads of leaves at the ends of the branches.

5. *Salix Helice Theophasti.*
Hungarian low Willow.

6. *Salix Alpina Pyrenæa.*
Low Willow of the *Pyrenean* hils.

This small Willow riseth unto scarse halfe a cubits height, with slender short branches, full of small long leaves, hairy all upon the edges, and as soft as Velvet, the stalke with the catkins thereon are an inch long, being soft and slender, but else like the rest.

7. *Salix Alpina repens angustifolia non incana.*
The greene creeping Willow.

The branches hereof, although some of them rise above the ground, yet take they roote below, having somewhat broad and long leaves on them, wholly greene, so that but that the flowers doe appeare like unto the rest, none would take it to be a Willow.

8. *Salix angustissimis & longissimis foliis.*
The longest leafed Willow.

This low Willow hath yellowish rods, with the longest narrowest leaves of any of the rest, white on both sides, but

some-

somewhat knobby underneath, this hath also scaly heads of leaves, at the ends of the branches as the fifth.

*The Place* and *Time.*

The first is alwayes planted in the low grounds that are often overflowen, where it onely will thrive: the other sorts, some are found growing with the last sort, or by them in sundry the said and the like places with us, and in *Hungaria, Austria, &c.* as *Clusius* and *Bauhinus* have set it downe.

*The Names.*

The first is called *Salix Vitellina* by *Cordus* on *Dioscorides*, and by *Dodonæus*, and is the third *Salix* of *Tragus* and *Cæsalpinus*, *Gerard* calleth it *aquatica*, as the fittest name to distinguish it from the rest, and so doe I: It is also called *Vincus a vinciendo. Lugdunensis* maintaineth it to be the *Salix Amerina* of *Pliny*, against *Ruellius* and *Matthiolus*, he should have said also, who would make the *Vitex* or *Agnus castus* to be the *Salix Amerina* of the Latines, because that among the bastard names in *Dioscorides*, it is there so set downe, but they differ much, as you shall here more in the next Chapter. For *Lugdunensis* saith that they of *Lyons*, and the Mountainers in *Savoy* do call it yet to this day, *des Amerines*, which they of *Paris* call *Osiers*, and they of *Normandy*, *des Ambres*. Some also, as *Lugdunensis* saith in the Chapter of *Grossularia* and *Salix*, would make the ὶξὸς of *Theophrastus* to bee *Amerina*, but *Ixos* or *Oesus* giveth *Vvas* as he saith, whose liquor he calleth οἰνωπὸν, not unlike to thicke blackish Wine, but enclining more to purple. The second is the first *pumila angustifolia* of *Clusius*. The third is his second, and the *Salix humilis repens* of *Lobel*. The fourth is so called by *Bauhinus* as it is in the title. The fifth is taken by *Lugdunensis* to be the *Salix Helice* of *Theophrastus*, and by *Bauhinus*, *Salix humilis capitulo squammoso*. The sixt and seaventh are mentioned onely by *Bauhinus*, and the last by *Lugdunensis*, and is his sixth sort. Their *English* names are fitted to every of them, as I thinke is fittest for them.

*The Vertues.*

I thought fit to shew you what particular property is in each of these Willowes altogether, and not to make many places or repetitions. All of these in generall are cooling, drying, thickning and binding: both the leaves and the barke, and the seede especially, are used for any of those effects, as to stanch bleeding of wounds, and at the mouth or nose, and spitting of blood, as also al other fluxes of blood in man or woman, and likewise to stay casting, and the desire thereunto, if the decoction of them in Wine be drunke: it helpeth also to stay thinne hot and sharpe, salt, distillations from the head upon the lunges, causing a consumption: the leaves bruised with some pepper and drunke in wine, doe much helpe the winde chollicke, the leaves bruised and boiled in wine being drunke, doth much stay the heate of lust, and wholly extinguish it, if it be long used both in man and woman, the seede also is of the same effect. The water that is gathered from the Willow while it flowreth, the barke being slit, and a vessell apt to receive it, being fitted to it, is very good for rednesse, and dimme eye-sight, and filmes that begin to grow over them, and stay the rheumes that fall into them, to provoke urine being stopped if it be drunke, and to cleare the face and skinne, of any spots or discolourings: the flowers saith *Galen*, have a stronger effect to dry up any fluxe or humour, being a medicine without any sharpenesse, and the barke much more, as all barkes doe, but if the barke be burnt and used, it doth yet dry more forcibly, and being mixed with vinegar, it taketh away warts, and cornes, and other the like flesh that groweth on the hands or feete, or other parts: the decoction of the leaves and barke in wine, is good to bathe the sinewes, as also the places pained with the gout, and to cleanse the head or other parts of scurfe, the juyce of the leaves and greene barke, mingled with some Rosewater, and heated in the rinde of a Pomegarnet is singular good to helpe deafenesse to be dropped into the eares: the seede of the blacke Willow mixed with litharge of silver in equall quantity, made into an oyntment and used on any place where the haire groweth that you would take away, after it hath beene bathed well before, or else in the baine or stove doth cause it to fall away. Of the twigges or rods are made many sorts of workes, both fine and course baskets, chaires, cradles, and many other the like: bands also both greater and lesser, to binde up Vines, Trees, Hedges, and many other things, hoopes also, and the small twigges, to binde the hoopes stakes also, and poles both high and low, to hold up or fasten hedges, bushes, &c. unto, and many more the like things. *Tragus* remembreth a pretty fained controversie betweene the Boxe and the Willow, written in the *Germane* tongue, whether of them were of the better use in the common wealth, or might best be spared. Of the Sallow especially, but of the other Willow trees in generall, the best coles are made to make Gunpouther withall, as is well knowne, and with the coles likewise, the finest Painters draw their first draughtes: the *Castor* or Bever delighteth chiefely to make his residence among the Willowes, and Osiers, in the Waters sides.

---

## CHAP. XXXIII.

*Spiræa Theophrasti Clusio. Clusius* his spiked Willow of *Theophastus.*

THis strange Willow (for so it is most like) groweth to be a small low bush of three or foure foote high spreading forth slender branches covered with a reddish barke, whereon are set without order, many long and narrow leaves most like unto the Willow, of a pale greene colour on the upperside, and browne underneath, finely dented about the edges, of a drying taste, with some bitternesse: at the ends of the branches come forth thick bushing spikes, or clusters of blush coloured flowers, consisting of five leaves a peece, with some threds in the middle, of the same colour, without any sent, which turne into small five square heads with very small seede like dust within them, of a yellowish colour.

*The Place* and *Time.*

This was sent out of *Silesia* to *Vienna* to *Clusius* by *Sibisius*, the Duke of *Briga*, his learned Apothecary, where it is most likely it grew, and flowred in *May* with *Clusius*, and the seede was ripe in *August*.

*The Names.*

*Clusius* saith he that sent it tooke it to be a *species* of *Syringa*, and questioned *Clusius* whether it should not bee referred

referred thereunto, but hee seriously considering thereon, could not finde it like to any plant that he knew, and therefore judged it most neerely to represent the ἀκτεῖνα or as, some reade it πάρατα of *Theophrastus*, which hee putteth among those trees that beare spikes, as *Spiræa*, *Erica*, *Agnus*, and some others *lib.*1. *c.*23. and withall *Clusius* saith that this doth more fitly agree to his *Spiræa*, then the *Viburnum Matthioli*, as some would have it.

*The Vertues.*

There are no property mentioned of this plant, whereunto it might be serviceable in Physick or otherwise, and therefore let this suffice.

*Spiræa Theophrasti forte Clusio.*
*Clusius* his spiked Willow of *Theophrastus.*

## CHAP. XXXIV.

*Vitex sive Agnus Castus.* The Chaste tree.

THe Chaste tree is of two sorts, one with narrower, and another with broader leaves the one dented and the other not, the one with whitish and the other with purplish flowers.

1. *Vitex folio angusto.* Narrow leafed Chaste tree.

This riseth up taller then a shrub, unto the height of a low tree, with divers branches covered with a darke coloured barke, and are lithy easie to bend, with sundry large leaves cut or divided like unto Hempe leaves, either into five or seven parts or leaves, each of them being long and narrow like Willow leaves but smaller, and not dented at all about the edges: at the ends of the branches come forth long spikes of flowers, somewhat like unto Lavander spikes, stored with blush white flowers at severall spaces up to the toppes, after which come small round seede, of the bignesse and likenesse almost of pepper, whereupon some have called it *Piper agreste*, but neerer unto Coriander seede, but of a blackish gray colour, and tasting somewhat hot and strong.

*Vitex sive Agnus castus folio angusto.*
The Chaste tree.

2. *Vitex folio latiore.* The broader leafed Chaste tree.

This groweth lower and lesser then the former, having the like leaves divided as it, but each somewhat broader, and dented about the edges, more white and woolly also then they, the flowers grow in spikes after the same manner, of a blewish purple colour, the seed that followeth is also like the other.

*The Place* and *Time.*

These grow in the further part of *France*, in *Italy*, and *Spaine*, usually by watersides and in the moister grounds, these colder Countries doe onely nurse them up in Gardens for their rarity and use: they flower in *Iuly*, and the seede is ripe in *August* in the naturall places, but will hardly flower with us.

*The Names.*

It is called in Greeke ἄγνος, that is, *Castus quod castitatem conservet ijs quibus aut estur, aut bibitur, aut substernitur* as *Galen* saith, or as *Dioscorides* saith, because the *Athenian* matrons, in their *Thesmophoria*, did use these leaves as sheetes to lye upon, thereby to preserve their chastity, the Physitians and Apothecaries, joyning both words together call it *Agnuscastus*, the Latines also call it *Vitex*, it is likewise called in Greeke λύγος, *Lygos quasi vimen propter invicta fere ramorum flexilitatem.* *Lobel* in *Adversaria* taketh it to be *Æleagnus* of *Theophrastus lib.*4.*c.*11. which he saith is like the other *Amerina*, but beareth no fruite, yet the flower is like the white Poplar flower, which how it may agree there with I cannot see, for

this beareth fruite in a plentifull manner in the naturall places. Some also would make it to be the *Salix Amerina*, as I said in the former Chapter, because *Gaza* translateth ἄγνῳ in *Theophrastus* unto *Amerina* in Latine, *lib.1.c* 5. and 22.and 23. from whence sprang that errour. Some also as *Lugdunensis* saith *fol.*133. would more truely make the ὅσιος of *Theophrastus* to be this ἄγνῳ *Vitex*, because of the different colours in the flowers of both, but as I shewed in the Chapter before, *Theophrastus* giveth white and blacke berries, as well as flowers, to his *Isos* or *Oesus*, whose liquor he calleth οἰνωπὸν a kinde of Wine, so that it can no way agree thereunto: all Authours call both these sorts *Vitex* or *Agnus castus*. The *Arabians* call it *Famanchest Samachest*, and *Bengiechest*, the *Italians Vitice*, and *Agno casto*, the *Spaniards Gatillo casto*, the *French Agnus castus*, the *Germanes Schaffs mullem*, and *Keuschlamp*, and we in *English* Chaste tree.

*The Vertues.*

The leaves and seede of the Chaste tree as *Galen* saith, is hot and dry in the third degree, and of a very thinne essence or substance, sharpe also and binding, for so it declareth it selfe to them that use it, yea the seede is perceived plainely to be so hot that it procureth headache, yet being parched or fryed it will the lesse trouble the head, besides it dissolveth the winde in the stomacke or belly being fresh, but being fryed or parched much more: it restraineth also the instigations to Venery in any manner used and taken: thus farre *Galen*, unto whom *Paulus* and *Ætius* doe consent affirming the same things. The seede being drunke resisteth the bitings of venemous beasts, Spiders or the like, and helpeth the dropsie, and those that are troubled with the spleene, it also procureth milke in womens breasts, it procureth their courses, and the urine stopped, if a dramme thereof in pouther be taken in Wine or with Pennyroyall: it troubleth the head and causeth sleepe: the decoction of the herbe and seedes is very good for women troubled with the paines of the mother, or inflammations of the parts: the hot fumes thereof taken underneath, is no lesse effectuall: applyed to the head it easeth the paines thereof, and with oyle and vinegar, the Lethargy, and Frensie: the same also made into a pulcis with Vine leaves, and applyed to the cods that are swolne and growne hard, doth helpe them: it is said to helpe an ague, being taken before the fit, and being annointed therewith made up with oyle to provoke sweate: the same also used to the limmes taketh away wearinesse upon travaile or labour: the leaves are almost as effectuall as the seede, for all the purposes aforesaid, and are good for wounds also: the seede used with Barley meale, doth mollifie hard swellings, and breake Impostumes: and with niter and vinegar it helpeth freckles of the face; used with honey it helpeth the sores in the mouth and throate. *Galen* although so famous a writer and Physition contraryeth himselfe in this one plant, once or twise, for having affirmed before that the seede hereof is hot and dry *lib.* 1. *Alimentorum*, he saith, having spoken of the properties of Hempe seede, that the seede of *Vitex* doth restraine Venereous desires, and giveth little nourishment to the body, and that because it is cooling and drying. In another place he saith (speaking of *Archigenes* medicines for the headache) among other things, that of the leaves of the Bay tree, the Poplar, and the *Vitex* or Chaste tree with vinegar and oyle, he made a medicine of differing properties: for the Bay tree leaves are very hot, and those of the Chaste tree moderately cold, and in the meane betweene both are the Poplar leaves: in both which places you see he maketh this Chaste tree to be cold, when before he had placed it; not among those that were temperate, but in the third degree of heate: yet some of good Wit to free *Galen* from this last errour, would invert the Text and say that the Bay leaves are the hottest, the Poplar the coldest, and the Chaste tree leaves a meane betweene them both.

## CHAP. XXXV.

### *Olea.* The Ollive tree.

THe Ollive is distinguished into the tame or manured Ollive, and into the wild sort: for although the old Writers as *Pliny*, *Columella*, and others set downe ten sorts, which they called by severall names, which whether it were in these as in the diversities of Vines, wee know not our climate not fitting their growing, or according to Wines, which according to the severall climates and soyles, gave sweeter or harsher, weaker or stronger Wine, one then another, and so greater or lesser Ollives, and sweeter or stronger oyle one then another: for divers doe account them to be differing in *specie*, one from another, as our Apples, Peares, and Cherries doe.

1. *Olea sativa.* The manured Olive tree.

The manured Ollive tree riseth in some place to be very tall, and very great, like a great Wallnut tree, in others not of halfe that height and greatnesse, with divers armes and branches, not very thickely set together, whereon grow somewhat long and narrow leaves like the Willowes but lesser, and shorter, thicke, fat, and sharpe pointed with short footestalkes under them, greenish above and whitish underneath, never falling off the tree, of a bitter taste and somewhat sharpe withall: the blossomes are many set together at the joynts with the leaves, small and of a greenish white colour, made of foure leaves a peece, after which come round and somewhat long berries, greene at the first, and changing pale afterwards, and then purplish, and lastly, when they are full ripe, of a deepe blacke, and some white when they are ripe, as *Clusius* saith he observed: some are great others are small, and some of a meane sise betweene both, some are longer, and some rounder then others, some are fitter to eate, and yeeld not much oyle, others are not so fit to eate, and are smaller, yeelding more store of oyle, some againe are gathered unripe and pickled up in brine, (which are the Ollives we use to eate with meate) others are suffered to grow ripe, and then pickled or dryed, and kept all the yeare, to be eaten as every one list: Of those Ollives whereof oyle is made, some oyle will be delicate sweete and neate, others more fatty or full and strong, some upon the taste will leave no bitternesse or heate in the mouth, but will taste as sweete as butter, others againe will be more or lesse hot and unpleasant in taste, the wood is faire, firme, and solid full of curld veines, and as apt to burne when it is greene as dry, and will not rot in a long time.

2. *Oleaster sive Olea sylvestris.* The wild Ollive tree.

This wilde Ollive tree groweth somewhat like unto the manured, but that it hath harder and smaller leaves, and thicker set on the branches, with sundry sharpe thornes among the leaves: the blossomes and fruite come forth

1. *Olea sativa.* The manured Ollive tree. 2. *Olea sylvestris.* The wild Ollive tree.

forth in the same manner that the other doe, and in as great plenty, yet much lesser, and scarse comming at any time to ripenesse even in the naturall places, but where they doe being ripe, they are small with crooked pointes and blacke: Of the Ollives hereof is sometimes made oyle, which is colder and more astringent inproperty then the other and harsher in taste, and greenish in colour, but the Ollives are much also respected and gathered to be eaten.

*The Place* and *Time.*

Both these grow in the warmer Countries onely, neither will they beare fruite in any cold climate, or rather scarse live out their Winters: the manured as I said before is wholly planted wheresoever it groweth, where according to the soyle and climate come greater or lesser Ollives, and more or lesse store, sweeter oyle also, or more strong in taste. Many doe thinke saith *Columella*, that the Ollive tree will not grow, or at the least not beare fruite if it doe grow, above three score miles from the Sea. For from the Isles in the Mediterrenean Sea, as *Zante* and *Cerigo*, *&c.* is brought the finest and sweetest oyle, and from *Majorca*, *&c.* a fuller or fatter oyle; from *Provine* in *France* a stronger and hotter tasted oyle, then either of them or some others: the wilde Ollive groweth naturally in *Spaine*, *Portugall*, *Italy*, and many other Countries. They flower in *Iune* and *Iuly*, and have not their fruite ripe untill *November*, or *December*, and as *Clusius* in *Granado* not untill *February*, the wilde in *Ianuary* and after. *Virgil* sheweth in these Verses that the Ollive being planted needeth no further dressing.

*Non ulla est Olivis cultura, neque illæ*
*Procurvam expectant falcem, rastrosque tenaces,*
*Cum semel hæserunt arvis, auras que tulerunt.*

*The Names.*

The manured Ollive is called in Greeke ἐλαία ἥμερος, and *Olea sativa* in Latine, the wilde Ollive ἀγριελαία, κότινος and ἀιθιοπικὴ ἐλαία, that is in Latine, *Oleaster*, or *Olea sylvestris Cotinus*, and *Olea Æthiopica*, as *Dioscorides* hath it: the fruite is called ἐλαία, and *Oliva* in Greeke and Latine, and when they are neere ripe *Drupæ*, and *Drupetes*, and *Colymbades* when they are pickled or dryed to be eaten, yet the Greekes at this day call them *Dermatia*. The manner to make Oyle as *Matthiolus* relateth is thus: after the Ollives are gathered they are laid a little to wither, and afterwards ground in a Mill, and then put into a strong presse, with some hot water powred on them to yeelde out the oyle, which after it hath stood and is settled, the pure oyle is drawne off from the foote or bottome and kept for use. The manner to pickle Ollives to have them keepe their greene colour, is saith *Matthiolus*, to take six pound of quicke Limestones made into pouther, which dissolved in so much water as may make it thinne, you are to put thereto twelve pounds of fine sifted Oke ashes, dissolved in as much water as will be sufficient, into which you are to put 25. pounds of fresh gathered greene Ollives, and let them lye therein eight or ten houres at the most, to take out their bitternesse, stirring them a little, and afterwards washed in many waters, shifted for five dayes together, which are lastly to be put into brine or pickle, wherein some Fennell stalkes and leaves have beene put into the boyling, and then put up into woodden or earthen vessels, as you list. The foote of the oyle is called *Amurca* in Latine. The gum saith *Dioscorides*, that the *Ethiopian* or wilde Ollive doth yeelde, is yellow, somewhat like unto *Scammony*, being in small droppes, and is hot or sharpe, biting upon the

tongue: but that saith he, which is blackish resembling *Gum Ammoniacum*, or other gum, and burneth not upon the tongue, is adulterate and false, but saith *Matthiolus*, this gum is neither brought us now adayes, nor is in use: yet some thinke that our Gum *Elemi* is it, but therein saith he they are much deceived, in that it hath no biting taste in it, and besides it is more like unto a Rossen that will melt with the fire, then a Gum which will burne in the fire, and will not be dissolved without wine or vinegar, or other such liquor. The *Arabians* call the manured Ollive *Zarton* and *Carton*, the *Italians Olivo domostico*, the *Spaniards Olivo* and *Azeytuno*, the *French Olivier*, the *Germanes Oelbaum* and *Olivebaum*, the *Dutch Oliveboom*, and we the tame or manured Olive tree: the wilde Ollive is called by the *Italians Oliva salvatica*, by the *Spaniards Azebuche*, and *Azuche*, by the *French Olivier sauvage*. And we in *English* the wild Ollive tree.

*The Vertues.*

The greene leaves and branches of the Ollive, but much more of the wilde Ollive doe coole and binde, especially the juyce with vinegar, all hot Imposthumes inflammations and swellings, Saint *Anthonies* fire, fretting and creeping ulcers, cankers in the flesh or mouth: the same also restraineth the bleeding of wounds, and womens too abounding courses, being applyed to the places: the said juyce dropped into the eyes, stayeth the destillations of hot rheumes into them, and cleereth the sight from filmes or cloudes that dimme the sight, and any ulcer that doth breede therein, or ulcers that breede in the eares. The pickled Ollives doe stirre up an appetite to meate, and although hard of digestion, yet pleasing to the stomacke, being apt to putrefie therein, are not good for the eyesight and breede headache, yet if they be dryed and applyed to fretting or corrhoding ulcers, doth stay them, and taketh away the scarres of carbuncles or plague sores: the pickled Ollives burned, beaten and applyed unto wheales, stay their further encrease, and hinder them from rising and cleanse foule ulcers, helpeth the gums that are loose and spongy, aud fasteneth loose teeth. The water that is taken from the greene wood, when it is heated in the fire, healeth the scurfe and scabbes in the head or other parts: the Olive stones being burned are used for the said purposes, and also to stay foule spreading ulcers, and being mixed with fat and meale, they take away the ruggednesse of the nailes. Now to speake of the other parts of the Ollive, which are the oyle and the foote thereof: first the oyle is of divers variable properties, according to the ripenesse or unripenesse of the fruite, whereof it is made, and then of the time and age thereof, and lastly of the washing thereof, from the salt wherewith some is made, the oyle that is made of unripe Ollives, is more cooling and binding then that which is made of them when they are ripe: which when it is fresh or new is moderately heating and moistening, but if it be old it hath a stronger power to warme and to discusse, which properties are perceived by the sweetenesse, for if the oyle be harsh, it is more cooling then warming: and if that oyle be washed it taketh from it all harshnesse. The greene oyle of unripe Ollives while it is fresh, is most welcome to the stomacke, it strengtheneth the gums, and fasteneth the teeth, if it be held in the mouth for any time, and being drunke it hindereth their much sweating that are given thereunto: the sweete oyle is of most use in Sallets and meates, being most pleasing to the taste, but the older the oyle is, the better it is for medicines, both to warme any part, and to discusse any thing that needeth it, and to open and moove the belly downewards, and is most effectuall against all poysons, especially those that doe exulcerate the guts, or not being passed downe so low, but yet abiding in the stomacke, it bringeth it up by vomitting, or hindereth the malignity, from further spreading: it is also a principall ingredient into all salves almost, helping as well the forme, as the vertue in working. The foote or dregges of oyle, the older it is the better it is for divers purposes, as to heale the scabbe in man or beast, being used with the decoction of Lupines: it is very profitably used for the ulcers of the fundament or privy parts, with honey wine and vinegar, it healeth wounds, and helpeth the toothache, being held in the mouth, if it be boyled in a copper vessell unto the thickenesse of honey, it bindeth much and is effectuall to all the purposes for which *Lycium* may be used: but if it be boyled with the juyce of unripe grapes to the thicknesse of honey, and applyed unto aking or corrupt teeth, it will cause them to fall out: if this foote or dregges of oyle be put into that morter that shall parget the walles or floores of your Wardrobs, where you meane to lay any woollen or silken stuffes or garments, in chestes or presses, it will not onely preserve the places dry, from gathering moisture, but warme also from over much cold, and will keepe away mothes, wormes, spiders, and flyes, nor will suffer any to breede therein. The gumme of the Ollive tree (whether tame or wilde) is used in ocular medicines to helpe the dimmesse of the eyes: the same also provoketh urine and womens courses, and helpeth the paines of hollow teeth: it causeth aborsement, it expelleth the dead childe, and healeth tetters, ringwormes, scabbes and lepry.

## CHAP. XXXVI.

*Oleaster Cappadocicus.* The bastard or sweete wilde Ollive.

THe bastard wilde Ollive, (and why I so call it I will shew you by and by) groweth by time to be a great tree, and well spread, whose barke is very rugged on the body, but smooth and whitish on the armes. which have very strong and sharpe thornes on them, the younger branches having none: the leaves are set on both sides of them without order, long and narrow, very like unto Willow leaves, but thicker, softer, and whiter, both the upper and under side, which enclineth to a silver shining colour: the flowers grow at the foote of the leaves, being small and of a pale white colour, very sweete and somewhat strong, sented even a farre of: after the flowers are falne, come round and somewhat long white berries, like unto small Ollive berries, with a point at the ends like unto thornes, with a sweete soft and spungy substance somewhat like a plumme, or the red *Iujube* fruite, having a chanelled hard stone, like an Ollive stone in the middle: but *Lugdunensis* saith the berry is as dry, and without substance as the Hawthorne, which peradventure is so in those places neere him, but in the warmer Countries may be such as I have described them, from good Authours that have seene them to be such.

*The Place* and *Time.*

This groweth as *Bellonius* saith in divers places in *Turkie*, as he saw in his travailes through their Countries, and in the hedges of *Granado* in *Spaine*, as *Clusius* observed, and in most Orchards of note in *France*, *Germany*, and other

other places with us also: and flowreth in the beginning of Summer in the warmer Countries, but very late with us the fruite ripeneth in Autumne in *Spaine*, *&c.* but seldome with us, yet *Matthiolus* saith, hee saw fruite on the tree that grew in the Emperours Orchard in *Vienna*.

*The Names.*

This tree is diversly taken by divers learned Writers, for *Matthiolus* calleth it *Olea Bohemica*, and taketh it to be *Eleagnus* of *Theophrastus*, because the name being deduced from *Olea* and *Agnus*, the Ollive and the Chaste tree, as like unto them both, this having leaves and branches like the Chaste tree, and berries like the Ollives: but that it cannot be *Eleagnus*, let me shew you that this is a great tree. *Theophrastus* saith it is *fruticosa planta*, a shrubby plant, and againe, he saith the flower of the white Poplar which all know, doth grow in spiked heads not scatteringly on the branches, and lastly he saith, it beareth no fruit, and this is plentifull in any of those places, where *Theophrastus* chiefly gathered his knowledge of this and other Plants, and therefore as *Theophrastus* saith, being so like unto the kindes of Willowes, it is most probable to a kinde of Willow, which are thought to beare no seede or fruite, and therefore *Amatus Lusitanus* would make it to be *Salix Amerina*, without any good ground or reason. *Bellonius*, *Clusius*, and *Camerarius* call it *Ziziphus alba Columellæ*, whereunto it is very like: *Gesner* also in *hortis* so calling it, and *Oleastri species quibusdam* also: *Bellonius*, *Dodonæus*, and *Lugdunensis*, take it to be the *Ziziphus Cappadocica Pliny*. which it is very probable to be also, *Lobel* calleth it *Olea sylvestris Septentrionalium*, and *Æleagnus* also, and some likewise *Olea Germanica*, but in my opinion *Lobel* and *Bauhinus*, and those in *Gesners* time do come neerest unto the name, whereby it may be most truely called *Olea sylvestris* or *Oleaster*, which I have followed and added *Cappadocicus*. because that in leafe it doth more neerely resemble the Ollive tree, then the *Iujube*, and that it is more naturall to be of *Cappadocia* then *Bohemia*, or any of these Northerly Regions: some also call it *Arbor Paradisea*, and some *Thuia odorata*, and some take it to be the *Barba Iovis* of *Pliny lib. 6. c. 18.* *Rauwolfius* saith it is called in *Syria Seisefan*.

*Oleaster Cappadocicus.*
The bastard or sweete wilde Ollive.

*The Vertues.*

We have no especiall Physicall property alotted unto this tree, or the fruite, but that as *Bellonius* and *Clusius* have recorded, the fruite is eaten by the people where they grow, with delight and pleasure, and without any offensive quality. The flowers as *Lugdunensis* sheweth, might be employed to perfume gloves, or garments, or to be distilled into a sweete water as well as the flowers of *Calef.* which *Bellunensis* tooke to be this tree, and are used in the manner aforesaid.

## CHAP. XXXVII.

*Oenoplia spinosa & non spinosa sive Napeca sive Ziziphus alba.*
The white *Iujube* tree, with thornes and without.

IN regard that this tree doth so neere resemble the other *Iujube* tree, mentioned here before in this Worke. I might have joyned them together, but that I could not assure it you to be of the same property, I have therefore reserved it for this place, as partly partaking with the Ollive as the Iujube tree, and is of two sorts, the one bearing thornes, and the other none, in all other things so like, that one description may serve them both. It groweth to be a tree as great as a meane sised Peare-tree, whose body and branches are covered with a whitish ash-coloured barke, full of small short and sharpe prickes or thornes, two set at each leafe not farre in sunder, in the one sort, and without any in the other: the leaves are somewhat broad and short, very like to the leaves of the other Iujube tree but greater, round pointed for the most part, with three ribbes in each, running all the length, of a darke shining greene colour on the upper side, and somewhat tending to an ash-colour underneath, standing singly at the branches, one on this side and another on that up to the toppe; at the joynts with the leaves come forth divers small greenish white flowers, like the blossomes of the Ollive or Iujube tree for the forme, each standing on its owne small footestalke, after which being falne come many small round fruite, as bigge as a great Cherry, yet sometimes as great as a Wallnut, in some whitish, in others more yellow, and reddish on the one side like an Apple, of a very sweete taste, with a stone in the middle thereof, like an Ollive stone, but round and not long.

*spinosa & non spinosa*

*The Place* and *Time.*

These grow in *Syria*, *Egipt*, *Arabia*, and the parts neere unto them, where they hold their greene leaves all the

Winter without falling, but in *Candy*, and other the hether parts, they have beene obſerved to fall off, as other trees doe: they beare in the warmer Countries twiſe a yeare, yet the former fruite that commeth in the Spring of the yeare, ſeldome commeth to maturity, becauſe the moiſture of the time ſpoyleth them, that they doe not ripen kindly, but in the Autumne the fruite is ripe and delicate.

*The Names.*

That ſort which is without thornes is deſcribed by *Alpinus* in his Booke of *Egiptian* plants, who calleth it *Nabca Paliurus Athenæi credita*, and very truely for *Athenæus* in the foureteenth Booke of *Deipnoſophiſtes*, calleth it *Paliurus*, and ſaith that *Agathocles*, in the third Booke of his Hiſtory, deſcribeth it by the name of *Connarus*, as thoſe of *Alexandria* called it, and by *Honorius Bellus* that ſent the fruite to *Cluſius*, as it is ſet downe in his fifth Epiſtle to him called *Oenoplia ſpinoſa*. That without thorne is ſet forth by *Cluſius*, in his Hiſtory of plants; as he received it alſo from *Honorius Bellus* of *Candy*, who calleth it *Oenoplia ſeu Napeca Belloriy Connarus Alexandrinorum forte Athenæi*: *Serapio* comprehendeth them both under the name of *Sadar* or *Sudar*, but as his manner is in other things, he confoundeth it with the *Lotus* of *Dioſcorides*, from which it much differeth, it is called in *Syria* and *Egipt*, *Nep* and *Nap*, and as *Guilandinus* ſaith, put by many among the ſorts of *Injubes*. But *Pliny* ſeemeth to call it *Prunus Ægyptiaca*, an *Egiptian* Plumme.

*Napeca Nabca aut Oenoplia ſpinoſa.*
The white Iujube tree with thornes.

*The Vertues.*

The fruite of both theſe before they are ripe, are cold and dry in the firſt degree, and binding, but when they are ripe they have ſome moiſture in them, and are much uſed to ſtrengthen the looſeneſſe of the ſtomacke and belly, by the juyce of them being taken at the mouth or given in a gliſter: the dryed fruit infuſed in water, and the infuſion taken, is profitable againſt the ſlipperineſſe and ulcers of the bowels, the decoction or infuſion of the ripe fruite, being dryed is of great uſe againſt peſtilentiall feavers, for the fruite is held to have a wonderfull property againſt venomous qualities, and to reſiſt putrefaction, and mightily to ſtrengthen the heart: the juyce of the fruite when it is throughly ripe, is very good to purge choller from the ſtomacke, and the firſt conduits of the veines: as alſo in all putride feavers, an infuſion of them is familiarly taken to coole the heate and violence thereof.

## CHAP. XXXVIII.

*Azadarach Avicennæ.* The Bead tree.

ALthough this tree be in forme much differing from any of the laſt ſorts, yet becauſe ſome have called it *Ziziphus*, as they did the laſt ſave one. I thought it not amiſſe to inſert it in this place, whoſe deſcription is on this manner. It groweth to be high and vaſte, ſpreading far and making a goodly ſhadow in the warme Countries where it beſt proſpereth, the body and greater boughes are covered with a rugged barke and full of chinkes, but that on the youuger branches, is ſmooth ſomewhat like unto thoſe of the Figge: the leaves are very largely ſpread and winged, having long footeſtalkes, ſomewhat like unto Aſhen leaves, but larger, more ſpread and of a darke greene colour, dented about the edges, the end leafe being longeſt, yet in ſome places they are not ſo largely ſpread, from the foote whereof come forth long ſtalkes, bearing ſundry blewiſh flowers laid open, with five ſmall narrow leaves like a ſtarre, and a ſmall hollow cup more purple in the middle, after which come round fruite, of the bigneſſe of a Cherry, greene at the firſt, and white when it is ripe, of a ſweetiſh taſte at the firſt, but after very bitter, unpleaſant, loathſome, and ſtincking, containing a ſtone within it ſixe ſquare, ſomewhat like unto the *Emblick Myrabolane* ſtone, with two kernels within each, from whence uſually riſe two ſproutes or ſtalkes of greene leaves, the fruite being drilled (which will be eaſily done, not being very hard) and drawne on ſtringes, ſerve people beyond Sea to number their prayers on, leaſt they forget themſelves and give God too many: this looſeth all his leaves in Winter, freſh ariſing in the Spring.

*The Place and Time.*

This groweth in none of theſe Chriſtian Countries naturally, but are all planted wherefoever they grow, in Orchards or Court yards, for the ſhadow ſake, being of little uſe beſide, *Cluſius* ſaith he ſaw divers of them in *Spaine*, and heard they were more frequent in *Italy*, it flowreth in *Iune*, and the fruite is ripe in *September*.

*The Names.*

This was called *Ziziphus candida*, by the Herbarists at *Mompelier* as *Lobel* saith, and *Sycomorus* by *Italians*, as *Matthiolus* saith, but misliking that title he called it *Pseudosycomorus*, yet in other places of *Italy* it is still called *Perlaro*. *Cordus*, *Gesner* in *hortis*, and *Bellonius* call it *Sycomorus Italorum*, *Lugdunensis* setteth it downe by the name of *Ziziphus alba*. *Gesner* saith some learned men called it *Myxus alba & Laurus Græca Pliny*. *Cæsalpinus* tooke it to be *Tuber candida*, of *Pliny*, and peradventure *Ziziphu Columellæ*, *Dodonæus* hath it under the name of *Azadarach*, and so have *Clusius* and *Camerarius*, some *Turkes* in these dayes call it *Thespic*, and *Rauwolfius* saith that they of *Tripoli* call it *Zenselacht*, but generally now adayes, with most *Azadarach* or *Asederaeth*, yet the *French* call it *Arbor sancta*, because as is before shewed, the fruite helpeth their devotions, as the *Spaniards* doe, that call it *Arbol parayso*.

*The Vertues.*

The best use that this serveth for is, that the distilled water thereof will kill Lice, and causeth the haire to grow faire and long, if it bee mixed with white Wine, and the headed washed therewith, the fruite is dangerous if not deadly, if it bee eaten causing the like Symptomes that the Oleander doth, and is to be remedyed with the same helpes: *Rauwolfius* saith, that it will kill dogges, if it bee given them with their meate.

*Azadaraeth herbariorum.*
The Bead tree.

## CHAP. XXXIX.

### *Phillyrea.* Mocke Privet.

OF this kinde of shrub there are foure or five sorts each differing from other in the broadnesse or narrownesse of their leaves especially, as you shall heare.

1. *Phillyrea latifolia aculeata.* Prickely mocke Privet.

This first Mocke Privet riseth up with sundry stemmes, of the thickenesse of ones thumbe, covered with a greenish barke spotted with white: the leaves are set by couples at the joynts, all along the branches, which are somewhat thicke, hard, and prickely, dented about the edges very like the leaves of the Scarlet Oke bush but greater: the flowers come forth at the joynts of the leaves, the fruite is small, and blacke round berries hanging downe about the branches, and are like unto the berries of Privet, or of the Masticke tree, but having a small stone within them.

2. *Phillyrea folio lato serrato.* Toothed Mocke Privet.

This other Mocke Privet groweth greater and higher, whose branches are covered with a whitish barke, having somewhat broad and hard blackish greene leaves, pointed at the ends and dented about the edges, two alwayes set at a joynt, of a little sharpe and bitter taste. The flowers grow at the joynts with the leaves, as in the former, and the berries that follow are blacke and round like Pepper or Mirtle berries, with a thin brittle sheld stone within it.

3. *Phillyrea latifolia foliis fere non serratis.* The greater Mocke Privet with lesse dented leaves.

This Mocke Privet groweth lower then the last, yet unto two mens height, with a whitish barke covering the branches as in the last, but somewhat more rugged. The leaves are set on the branches in the same manner as the former, but somewhat narrower, and but seldome dented at al about the edges, the flowers are of a whitish green colour, standing thicke together, about the setting on of the leaves, somewhat like unto the Ollive blossomes, after which come round berries like the last.

4 *Phillyrea angustifolia prima.* The first narrow leafed Mocke Privet.

This is a low bush not exceeding a mans height, but fuller of branches, yet smaller then the last, and covered with a blacker barke: the leaves are narrower and greener then it, like unto the wild Ollive, and not without some bitternesse in them: the flowers are white and grow after the same fashion, thicke set together, unto which being falne succeede blacke round berries like unto Mirtle berries, with a hard stone in them.

5 *Phillyrea angustifolia secunda.* The other narrow leafed Mocke Privet.

This other Mocke Privet shooteth forth many more suckers from the roote, which are slenderer and not very easie

1. *Phillyrea latifolia aculeata.*
Prickely Mocke Privet.

4. *Phillyrea angustifolia prima.*
The first narrow leafed Mocke Privet.

easie to breake, nor so plentifull or thicke growing as the former, with leaves set one against another, narrower, longer, and of a darker greene colour, this was said to beare neither flower nor seede, which matter is disproved, and found to beare both, and like unto the last.

*The Place* and *Time.*

*Clusius* observed these five sorts in *Spaine*, *Portugall*, and *France*. They flower in the Spring, and their berries are not ripe untill it be very late in the yeare.

*The Names.*

Divers learned men did take the φιλύρα *Phillyra* of *Theophrastus*, which we have shewed you to be the Line tree, to be this φιλυρέα *Phillyrea* of *Dioscorides*, being deceived by the vicinity of the names untill *Cordus*, who better considered them, found them much to differ, as well in forme as in properties, since whose time all that have followed him have so accounted of them. *Lobel* saith, he would rather read it φιλελαία or *Olea amasia*, a kinde of wilde Ollive, whereunto it is most like, or little differing: The first is the first *Phillyrea* described by *Clusius*, and so is my second hic second *Phillyrea* also: The third is the first *Phillyrea* of *Matthiolus* and *Lobel*, and the third with *Clusius*, and is the *Phillyrea* of *Bellonius*, and *Gesner in hortis*, *Dodonæus* calleth it *Cyprus latiore folio*, and *Lugdunensis Alaternus major Dalechampij*, and of *Cæsalpinus Ilatrum*, and *Phillyra* of *Theophrastus*, *Bauhinus* calleth it *Phillyrea folio Ligustri*. The fourth is the fourth *Phillyrea* of *Clusius*, the *Phillyrea angustifolia* of *Lobel*, the *Alaternus minor Dalechampij* of *Lugdunensis*, and the *Cyprus* of *Dodonæus*. The last is *Clusius* his fifth *Phillyrea* also, and both these last are called by *Lobel*, *Narbonensis*.

*The Vertues.*

The leaves of this Mocke Privet are binding, as *Dioscorides* saith, and are of the same effect that the wilde Ollive

2. 3. 5. *Philly folio lato serrato, & fere non serrato, & angustifolia secundas.* Toothed Mocke Privet, and with lesse dented leaves, and the other narrow leafed Mock Privet

tree

tree leaves are, and used in decoctions are good against the ulcers in the mouth or to wash the teeth, the same also being drunke provoketh urine and womens courses.

## CHAP. XL.

*Alaternus sive Philyca Theophrasti credita.* Ever greene Privet.

THere is so great affinity betweene the former Mocke Privet, and this ever greene Privet, that divers good Authours call the one by the others name, as you have in part heard in the former Chapter, and shall more in this, whereof there are two sorts a greater and a lesse.

1. *Alaternus major seu prior.* The greater ever greene Privet.

The former of these two shrubs, groweth sometimes tall like a tree, with long but not any great branches, nor yet much divided into lesser ones, and are covered with a whitish greene bark, and with another yellowish one under it, or more inward, whereon grow somewhat broad leaves without any order, of a meane sise betweene the Ollive, and the ever greene Oke, but thicker, and slightly dented about the edges, and of a darke greene colour, of an unpleasant taste, and bitterish withall, the flowers are many tufting together at the setting to of the leaves, and are of a whitish greene colour, there hath not beene any fruite observed to follow them.

2. *Alaternus minor seu alter.* The lesser ever greene Privet.

This other groweth lower by much, with a whitish greene reddish barke mingled, the leaves are lesser, rounder, and dented about the edges, and of a paler greene colour, the flowers are greater and greener, set together like the former, unto which succeede small round berries, greene at the first, reddish afterwaards, and blackish when they are ripe, having three stones or seedes within each of them.

*The Place and Time.*

Both these were observed by *Clusius* in *Spaine* and *Portugall*. They flower there in their naturall place in *February*, and the fruite is ripe in *May*.

*The Names.*

*Pliny* calleth this *Alaternus quasi inter Oleum & Ilicem media*, *Bellonius* in his first booke of Observations and 42. Chapter saith, that there is none in mount *Athos* but knoweth the true name of that tree, that *Pliny* calleth *Alaternus*, to be the *Philyca* of *Theophrastus*, but those of *Corcyra* and *Candy*, call it ἐλαιόφευν & *Elæprinus*. It is the first *Alaternus* of *Clusius*, and the *Alaternus Plinij* of *Lobel*, *Cæsalpinus* as *Bauhinus* saith, but I thinke rather it should be *Lugdunensis*, calleth it *Celastrus mas Theophrasti*, and *Cæsalpinus Phillyra mas Theophrasti*: *Lugdunensis* taketh it to be *Apharca Theophrasti*, which they of *Mompelier* call, as saith *Lobel*, *Bourgespine* some also call it *Phi-*

1. *Alaternus major.* The greater ever greene Privet.

2. *Alaternus minor.* The lesser ever greene Privet.

*lyrea,*

*lyrea.* The other is called by *Clusius Alaternus alter*, by *Lugdunensis Celastrus fœmina Theophrasti*, and both of them *Phillyrea* by *Bauhinus*, not giving any peculiar title to *Alaternus*, it is likewise the *Vaccinium Plinij*, and *Lacatha Theophrasti*, as *Lugdunensis* taketh it, some read *Lacara*, who saith it differeth much from all the other sorts of wilde Cherries, both in the forme of the leaves, bitternesse of the fruite, &c. and *Ilatrum folio ad Ilicem accadente* by *Cæsalpinus*, from the word *Iletro*, whereby the *Italians* of *Lucca* call it as *Clusius* saith, but *Anguilara* saith *Alatrerno*, and *Linterno*, as *Bourgespine* is by the *French* as *Lobel* saith, and yet I finde that name given to many other plants, but *Dalnder* and *Sanguin blanc*, as *Bellonius* saith, for as *Clusius* saith, the *Portugalls* call the first *Caseca*, and the other *Filiguero*, and *Sanguentio*.

*The Vertues.*

*Theophrastus* saith that *Philyca* hath the priority to feede sheepe in that it is ever greene: And *Clusius* saith that the *Portugals* use the barke to dye their nets into a red colour, and with the chips of the wood which are whitish they dye a blackish blew colour.

## CHAP. XLI.

### *Ligustrum.* Privet.

BEcause our Privet hath beenē so often mistaken by many for the *Cyprus* of *Dioscorides*, *Pliny* being the first Authour of the errour, who although *lib.* 12. *c.* 25. he saith that *Cyprus* is a tree that groweth in *Egipt*, with a white sweete flower, and Coriander like seede, yet presently after he saith, that some take this to be the same, which is called *Ligustrum* in *Italy*, and *lib.* 24. *c.* 10. hee saith plainely that *Ligustrum* is the same tree that *Cyprus* is in the East. I thinke it fit to joyne that *Ciprus* of the East in this Chapter with the other sorts of Privet that you may plainely know the diversity, and that all further controversies may cease.

1. *Ligustrum vulgare.* Our common Privēt.

Our common Privet growēth not into any great bodyed tree, but yet it is carryed up with the many slender branches to a reasonable height and breadth to cover Arbours, Bowres, and Banquetting houses, and brought wrought and cut into many formes of men, horses, birdes, &c. as the workeman list supported at the first with timber, poles, and the like, but afterwards groweth strong of it selfe, sufficient to hold it in the forme it is made into: it beareth long and narrow darke greene leaves by couples, and sweete smelling white flowers in tufts at the

1. *Ligustrum vulgare.* Our common Privet.

3. *Ligustrum Orientale sive Cyprus Dioscoridis & Plinij.* The Easterne ever greene Privets.

ends

ends of the branches, which turne into small blacke berries that have a purplish juyce within them, and some seedes that are flat on the one side with a hole or dent therein. *Tragus* saith that there is some found that beareth a yellow flower, but is very rare to finde differing in nothing else, which peradventure may be that other sort that *Lonicerus* calleth *minus*. *Alterum minus flore subluteo.*

2. *Ligustrum myrtifolium Italicum.* The *Italian* Mirtleleafed Privet.

This groweth in the same manner that the former doth, and spreading into branches that are round and somewhat reddish, the leaves are both longer and broader, comming neere unto the greatest Mirtle leaves, and of a darke greene colour.

3. *Ligustrum Orientale sive Cyprus Dioscoridis & Plinij.* The Easterne ever greene Privet.

This East Country Privet, if it be suffered to grow at large without pruining, groweth to be as great as the Pomegarnet tree, whose body and branches are covered with a whitish ash-coloured barke: the leaves are somewhat like unto those of the former common Privet, but whiter, broader and more pointed, growing many set on both sides of a stalke below, but singly up to the toppe at the joynts among the branches of flowers, which grow in a loose tuft, somewhat sparsedly, consisting of foure small grayish ash-coloured leaves, of a very sharpe and quicke sent, farre beyond the Privet flowers, after which succeede small round and white heads, somewhat like unto Coriander seede, with three or foure blackish seedes within them: the leaves fall not of in Winter as our Privet doe, but abide on fresh all the Winter long, of which and the young branches being dryed and ground into pouther, is made a great merchandise through all the parts of the *Turkish* Empire, and some of his bordering neighbours also, to give a yellow colour to their haire, hands, nailes, and bodies too, as also for their horses maines and tailes, for the more pompe on festivall dayes: of the rootes saith *Rauwolfius* being burnt, the *Arabians* make their *Spodium*, whereof *Avicen* speaketh *cap.* 617.

*The Place* and *Time.*

Our common Privet groweth in our owne Land, in divers woods, the next was sent from *Padoa* and *Venice*, the last groweth in *Egipt* plentifully, in *Tripoli* also and *Syria*, in sundry places: our Privet flowreth in *June* and *Iuly*, the berries are ripe in *August* and *September*: the last flowreth late even in the warme countries, and the seede ripeneth accordingly: the other hath not as yet beene discerned so exactly.

*The Names.*

This our ordinary Privet as I said before, was usually taken by *Tragus*, *Cordus*, *Ruellius*, *Matthiolus*, *Amatus Lusitanus*, and *Anguilara* who yet doubteth of it, to be the κύπρος *Cyprus* of *Dioscorides*, which *Pliny* also nameth, but *Fuchsius* as I take it, first doubted of it, and denyed it to be *Cyprus*, and denyeth also that it is certainely knowne by what name the *Ligustrum* of the Latines was knowne to the Greekes, and therefore *Dodonæus* after *Anguilara*, doe appoint *Phillyrea* to be it: but *Pliny* in saying *Ligustrum* is the same tree, that *Cyprus* is in the East, as is before said, bred this errour in so many: but *Cyprus* of *Dioscorides* is said by him to be a tree, but Privet is not so, it is a tree growing in *Egipt* saith *Pliny*, the best is in *Canope* and *Ascalone* saith *Dioscorides*, whereby they both judged it to be a strange tree, and not naturall of *Italy*, as *Ligustrum* Privet is. It hath saith *Dioscorides* Ollive like leaves but broader, softer, and greener, *Pliny* saith like Iujube leaves, but Privet leaves are neither broader nor softer then the leaves of the Ollive tree, the seede said *Pliny*, is like Coriander seede, which is meant by the whole seede, with the outer huske on it, for the seede within them is blacke, as *Dioscorides* compareth them to the seede of the Elder berries: the leaves also doe abide alwaies greene, but in Privet they doe not so: the leaves saith *Dioscorides* doe give a reddish yellow colour to the haire, if they be moistned with the juyce of *Struthium* (but not of *Struthei mali* which is the Quince) before it be applyed, but Privet giveth no such colour howsoever used: by all which notes it is evident that *Ligustrum* and *Cyprus* be different one from the other, and cannot be both one plant, or hereafter to be confounded together as formerly they have beene. The first is acknowledged by the name of *Ligustrum* by all Writers, although some as I said would make it also to be *Cyprus* of *Dioscorides*, and some to be *Phillyrea* as is before said. The second *Bauhinus* calleth *Ligustrum myrtifolium Italicum*, and saith it was sent him by the name of *Myrtus ligustri folio* The last *Bauhinus* calleth *Ligustrum Ægyptiacum latifolium*, because he maketh two sorts of this one, as he doth in many other things before, making that of *Rauwolfius*, set forth in *Bellonius* his Observations by *Clusius*, to be one sort, and that of *Alpinus* another, entituled *angustifolium*, because *Alpinus* his figure (as most of his others are) is not so exactly drawne, as *Clusius* saith it should be: he saith also that it is set forth in the history of the East Indies, *part.* 4. *figura tab.* 15. under the name of *Mangostans*: but the truth is, they were both entended but for one plant, *Alpinus* saith that the *Egiptians* doe now adayes call it *Elhanne*, and *Avicen* with the *Arabians* *Alcanne* and *Henne*, the Greekes now adayes *Schenna* as *Rauwolfius* saith. The *Italians* call the ordinary Privet *Giustrico*, *Olivella*, *Olivetta*, and *Chambrossena*, the *Spaniards* *Alfena* and *Alhena*, the *French* *Troesne*, the *Germanes* *Rheinweyden*, *Beynholtzlin*, and *Mundholtz*, the *Dutch* *Keelcruyt*, and we in *English* Prime or Privet, and of some Prime print.

*The Vertues.*

Although our ordinary Privet is little used in physicke with us in these times, more then to be put into lotions to wash sores and sore mouthes, and to coole inflammations and dry up fluxes, yet *Matthiolus* saith that Privet serveth to all the uses, for which Cyprus or the East Privet is appointed by *Dioscorides* and *Galen*: he further saith, that the oyle that is made of the flowers of Privet infused therein and set in the Sunne, is singular good for the inflammations of wounds, and for the headache comming from choller or an hot cause: a water also that is sweere is destilled from the flowers, that is good for all those diseases that neede cooling and drying, and therefore helpeth all fluxes of the stomacke or belly, bloody flixes and womens courses, if it be either drunke or applyed, as also for those that void blood at their mouth, or at any other place, and for destillations and rheumes into the eyes, especially if it be used with *Tutia*: All these properties may safely be transferred to the East Privet, saving that it is not of so cold a constitution, yet as *Galen* saith it hath a binding quality from the earthly cold substance it hath: the young leaves and branches are of a mixt temper, for it hath a digesting faculty with the warme watery substance and drying, whereby it helpeth those places that are burnt, and cooleth hot Impostumes and sores, and doth dry without any sharpenesse: the pouther of the leaves serve to heale the sores in the mouth or secret parts of man or woman, as also to helpe the moist sweatings and stinke of the feete, by applying them as a plaister mixed up with sweete wine: the *Oleum Cyprinum*, that is sweete and made thereof, doth warme and mollifie the nerves and sinues,

## CHAP. XLII.

### *Celastrus Theophrasti.* The Staffe tree.

THis tree groweth up to a meane height, the barke of the body and elder boughes being of a darke colour, and the younger greene, whereon are divers leaves, not greater then those of the fruitelesse Privet, and divers smaller, of a sad greene shining colour on the upper side, and paler underneath, which are little or nothing snipped about the edges, and of a little bitter taste: at the foote of the leaves towards the ends of the youngest branches come forth short stalkes of an inch long, sustaining five or sixe flowers, consisting of foure yellowish greene leaves a peece, which turne into small berries, of the bignesse of Asparagus berries, greene at the first, and as red as the Asparagus afterwards, but growing ripe are very blacke, and somewhat long with the roundnesse, wherein is contained a three square seed, like unto a Grape kernell, whose shell being hard hath as white a firme kernell within it as the hasell nut, covered with a saffron like yellowish skin.

*Celastrus Theophrasti.* The Staffe tree.

*The Place* and *Time.*

This grew at *Leiden* in the publike garden, but from whence the naturall place is, is not knowne: but from them hath beene communicated unto divers in this Land, as well as in others: the flowers doe often appeare so late that the fruite cannot come to ripenesse, yet it is signified that the first ripe fruite that was seene growing thereon was in *August.*

*The Names.*

Although *Lugdunensis* referre the κήλαστρον or κήλαστον of *Theophrastus* (for he hath both words) unto the *Alaternus* of two sorts that *Clusius* hath set forth, as is before shewed you, yet *Clusius* himselfe judgeth this tree to come neerer thereunto, then either of them, and so setteth it downe in his *Curæ posteriores*, some as he saith would make it a kinde of *Laurus Tinus*, but that it cannot be: I doe not find that *Bauhinus* Who setteth downe all other mens observations, hath once remembred this plant to referre it to any other, or make it one of it selfe, which is not usuall with him in many other that I know.

*The Vertues.*

*Theophrastus* recounteth all the properties hereof, whereunto it is put, and that saith he, is to make staves for old men, no other having made triall of any other faculty it is endued withall.

## CHAP. XLIII.

### *Viburnum.* The pliant mealy tree.

*Viburnum.* The pliant mealy tree.

THis pliant tree hath from a small body, rising to the height of a hedge tree or bush, covered with a darke grayish barke, sundry small (or not great) short, but very tough & pliant branches, of a fingers thicknesse, whose barke is smooth and whitish, whereon grow broad leaves like unto the Elme, but somewhat long aud hoary rough, thicke, white like meale, and a little hairy withall, set by couples, finely dented about the edges: at the ends of the branches stand large tufts or clusters of white flowers, which turne into large bunches of round and flat seed like unto Lentils but greater, greene at the first, and red afterwards, but blacke when they are ripe: the branches herof are so tough and strong withall, that they serve better for bands to tye bundels or any other thing withall, or to make wreathes to hold together the gates of their fields, then either withy or any other the like.

*The Place* and *Time.*

It groweth as a hedge bush, being often cut and plashed by the Countrymen, to spread on the hedges in length to hinder it of the height, and is found very much in *Kent*, and in other shires of the land. And flowreth not until the end of *May*, and ripeneth the fruite in *September.*

The

*The Names.*

Although the signification of *Viburnum*, doth properly entend the young twigge or shoote from the roote of a tree, yet it is not improbable that *Virgil* in citing these verses. *Quantum lenta solent inter Viburna Cupressus*, should meane this tree also, called *Viburnum*, (that it might hold his comparison to the Cypresse, of the meanenes of other Cities unto the statelines of *Rome*) as divers learned men think, which are *Gesner*, *Matthiolus*, *Camerarius*, *Durantes* and *Lugdunensis*, *&c.* and because that the *Italians* in their vulgar tongue, call it *Lantana* (*quod lenti sunt rami*) *Guilandinus*, *Gesner*, *Lobel* and *Cæsalpinus*, are content to cal it *Lantana* also, yet *Ruellius*, in writing of the *Rhus* of *Theophrastus* and *Dioscorides*, saith he found it without *Paris*, which the Country people called *Blanche putain*, and both he and *Lobel*, doe call it *Viorna Gallorum*, as peradventure derived from *Viburnum*, and yet they call another ramping bush *Viorna* also, which I have shewed you before among the clamberers, to be the *Atragene* of *Theophrastus*, unlesse the *French* have two *Viorna's*, which is doubtfull, for *Ruellius* sheweth a shrub, which he saith the *French* call *Blanche putane*, and is the same they call, saith he, *Viorne* and *Hardeau* also, *Lugdunensis* saith that *Dalechampius* did take this to be the *Speiræa Theophrasti*, because the pliant tough twigges may be writhed (in *spiras*) into wreathes or round circles: but as I shewed you before, *Clusius* setteth forth another *Speiræa*, which he taketh to be the truer. *Cæsalpinus* and *Ruellius*, doe both thinke it to be the *Rhus Theophrasti*, *lib.* 3. *c.* 18 which *Gaza* translateth *Fluida* from the Greeke word ῥοῦς, but as they thinke is no sort of our *Rhus*, or *Sumacke*, because he there describeth it with the leafe of the Elme, but longer, &c. and therefore they both referre it to this plant. *Matthiolus* saith, he was also of that opinion, untill having better perused *Theophrastus*, he refused that opinion, acknowledging himselfe to have beene in an errour. The *Italians* as I said, call it *Lantana*, and *Viburno*; the *French Viorne*, as *Ruellius* saith, and *Hardeau* also, from the *French* word *Hard*, which signifieth a band or rope, the *Germanes* call it in some places *Schlingbaum*, but *Tragus* and *Lonicerus*, *Kleiner Malbaum*, *Gerard* calleth it in *English* the Waifaring tree, but I know no travailer doth take either pleasure or profit by it, more then by any other of the hedge trees. I have therefore from *Tragus* his mealy tree, put to the pliantnesse of the twigges and branches, and called it the pliant mealy tree.

*The Vertues.*

The leaves of this tree are harsh and binding, and are good to strengthen and fasten loose teeth: the decoction of the leaves hereof, and of Ollive leaves together in vinegar and water, is of excellent good use to wash the mouth and throate that are swelled by sharpe rheumes falling into them, it is good also to set the *Vvula* or palate of the mouth into the right place, and to stay rheumes that doe fall upon the jawes: the kernels of the fruite hereof, taken before they are ripe, dryed and made into pouther and drunke, doe stay the loosenesse of the belly, and all other fluxes. Of the rootes being steeped under the ground, and then boyled, and beaten a long time afterward, is made Birdlime, with which Fowlers use to catch smaller birds: the leaves boyled in lye, and the head or haires washed therewith doth keepe them from falling, and will make the haires blacke.

## CHAP. XLIV.

*Sumach sive Rhus.* Sumacke.

THere are three or foure sorts of Sumacke to shew you, three of them of auncient knowledge and use, but one other of later invention: whereunto I must adjoyne another plant, which both for the names sake, and some likenesse thereunto, hath caused divers learned men to intitle it by their name.

1. *Sumach sive Rhus obsoniorum & coriariorum.* Coriars Sumacke.

The Coriars Sumacke in some places riseth to be a reasonable great tree (but in dry barren grounds not above two or three cubits high, or where it is yearely or every other yeare pruined for the profit made of them) spreading sundry branches with large winged leaves, that is many set on both sides of a middle ribbe, each of them dented about the edges, *Theophrastus* compareth them to Elme leaves, but lesser and longer, and *Dioscorides* to the leaves of the *Ilex*: at the ends of the branches come forth large spiked clusters of whitish flowers, which afterwards become reddish, round and flat seede like unto Lentils, with an outward skinny huske, which was, and is yet still in divers places in *Turky*, the condiment or seasoning for meate, being dryed and made into pouther: the wood is whitish, which being dryed and ground serveth to dye blacke withall, as is well knowne to most.

2. *Sumach sive Rhus Virginiana.* *Virginian* Sumacke.

The *Virginian* Sumacke groweth up in some places to be a tree of a meane size whose barke on the body and elder armes is rugged, and of a darke russet colour, those that are two or three yeare old, are smooth and not rugged, but those of the last yeare are of the same brownish red colour and softnesse, that the new velvet head of a deare sheweth to have, (that it might deceive a right good Woodman to see one cut of and presented him on the suddaine, yeelding a yellowish milke, when it is broken or wounded, which in a small time becommeth thicke like unto a gumme: the long winged leaves grow one above another on both sides of the branches very largely spread, having eight or tenne or more long narrow leaves set on each side of a middle ribbe, and one at the end, very smally dented about the edges, of a darke greene shining colour on the upper side, and paler greene underneath: at the ends of the branches come forth long and thicke browne tufts or heads, very soft and woolly in handling, made all of short threds or thrummes, from among which appeare many small flowers much more red or crimson then the tufts, which turne into a number of very red round flattish seede, thicke and close, set on the branches of the head together, lesser then the small Lentils, having a small blackish seede, under that outward skinny huske, whose shell is somewhat hard, enclosing a white kernell within it. the roote spreadeth much under ground, shooting forth suckers round about, and a good way of from the body of the tree.

3. *Rhus Plinij Mirtifolia.* Mirtle leafed Sumacke.

The Mirtle leafed Sumacke groweth seldome above the height of a man having many slender branches with leaves set thereon every one of the bignesse of the broad Mirtle leafe, set by couples, but not so closely, or alwayes just opposite one to another, nor so many together, and not dented about the edges: at the ends whereof come

forth many ſmall purpliſh red threds, ſet upon or ſticking out of a ſmall head, one ſet above another, which afterwards turneth into a round and ſomewhat flat creſted blacke berrie, containing therein ſmall white and rough ſeede, ſomewhat like unto Grape kernels. This in ſome places dyeth downe to the ground every yeare, and ſpringeth anew, which is the cauſe it can give no flower, much leſſe ſeede, which never is found on the firſt yeares ſhoote in our Country, but in other places of our Land ſheweth flowers, ſuch as I have deſcribed, but never any fruite that I can learne.

4. *Coggygria ſive Cotinus Coriaria.*
*Venice* Sumacke.

The *Venice* Sumacke is in ſome places a tree, riſing to be of the bigneſſe of the Pomegarnet tree, in other places it is much lower, and ſhooteth forth many twigges, of two or three cubits long, and of the bigneſſe of ones finger, divided into many reddiſh branches, having ſundry leaves ſet on both ſides without order, ſomewhat broad, round pointed, thicke, and full of veines, and ſmall red footeſtalkes under them, a little waved about the edges, of a Roſſenlike ſent, not unpleaſant, and of an harſh binding taſte, growing to be of an excellent Roſe colour, in the end of Summer; from the ends of the branches ſtart forth a large and long head, conſiſting of many tufts, of whitiſh greene flowers, ſtanding upon very fine red footeſtalkes, which afterwards ſpread themſelves into ſo many tufts of feather-like haires or threds, having among them ſundry ſmall blackiſh and flat ſeede, formed ſomewhat like unto an heart, which together with the ſilken threds are carried away by the winde: the roote is hard and wooddy, not growing deep nor much ſpreading: the wood is yellowiſh, and ſerveth to give a yellow dye: but the

1. *Rhus obſoniorum & coriariorum.*
Coriars Sumacke.

2. *Rhus Virginianum.*
Virginian Sumacke.

3. *Rhus Plinij Mirtifolia.*
Mirtle leaſed Sumacke.

leaves

4. *Coggygria sive Cotinus Coriaria.* Venice Sumacke.

5. *Rhus sylvestris sive Myrtus Brabantica aut Anglica.* Sweete Gaule.

leaves and young branches, doe Dye a blacke colour; and with the barke they Tanne leather, as with the other.

5. *Rhus sylvestris sive Myrtus Brabantica aut Anglica.* Sweete Gaule.

This other plant which as I said is fit to be joyned to the rest, is a small low shrub or wooddy bush, not above a yard high, spreading slender branches; with many browne yellowish greene leaves somewhat long, narrow, thicke and fattish, round pointed, resembling both Boxe and Mirtle leaves in some sort, but smelling somewhat strong and sweete, the flowers are yellow, and stand upon short stalkes, comming forth at the joynts with the leaves in small tufts, many set together, which being past, the said stalkes are plentifully stored with cornered yellowish seede, bedewed with a clammy moisture, of a very bitter unpleasant taste, but strong sweete sent: the roote is hard and wooddy.

*The Place and Time.*

The fiest groweth in *Syria* and *Pontus*, as *Galen* saith; in *Italy* and *Spaine* as *Pliny* saith, and in divers other places, where it is manured as carefully as their Vines, and as *Clusius* saith he saw it so ordered in *Spaine*, which yeelded the Owners great profit, the second groweth naturally in *Virginia*, from whence we had it. The third about *Mompelier*, and in sundry other places. The fourth in *Savoy*, and on the *Appenine* hils and elsewhere. The last groweth in many places of our owne Land, as well as beyond the Sea, as in *Sussex*, *Hartfordshire*, and *Kent*, and by old *Windsor* Parke corner.

*The Names.*

It is called in Greeke ῥοῦς, and by *Hippocrates* ῥόος, in Latine also *Rhus*, for *Pliny* saith it hath no Latine name although *Gaza* calleth it *Fluida* supposing the name to be derived from ῥέω *fluo*, but it is rather a *rubore vel colore coccineo acinorum*, and therefore it was called ἐρυθρός, from whence the Latine *Russus*, and the *French Roux* came. It is called *Rhus* simply by some, as *Matthiolus &c.* *Rhus coriaria* by *Dodonæus*, and *Rhus obsoniorum* by *Lobel*, *Camerarius*, *Clusius*, and others, and *Sumach* both by shops and in *Rauwolfius*, or *Sumach Arabum*, because it was called *Rhus Syriaca* by some, it was thought to differ from the former, as also, that *Rhus culinaria* and *coriaria* or *rubra*, did differ one from another, and were severall sorts, but *Paulus Ægineta*, doth plainely shew that the seede and juyce of *Rhus coriaria* was used by Physitions: another errour *Celsus* shewed, that tooke the *Rhus Syriaca* to be *Ros Syriacus*, a kinde of *Manna*, and therefore called it *rorem Syriacum*, instead of *Rhoem Syriacum*, and *rorem sutorium* for *Rhoen Syriacum*, or *coriariorum*, not *sutorum*, as it is in *Columella*: neither should it be *Ros marinus*, but *Rhus marinus*, or *Rhus Orientalis* in *Marcellus* who appointeth it for disenteries and the like. The second hath not beene set out by any before me, onely *Bauhinus* seemeth to touch upon it, calling it *Rhus angustifolium*, saying it was brought out from *Braffile*. The third is thought by most to be the *Rhus sylvestris* of *Pliny*, that hath Myrtle like leaves, and so called by *Lobel*, *Dodonæus*, and *Lugdunensis*, and *Rhus Pliniy Myrtifolia Monspeliensium* by *Gesner* and *Lobel*: yet some doe thinke it better agreeth with the *Dryophonon* of *Pliny*: the fourth is the κοκκυμηλέα of *Theophrastus*, which *Gaza* translateth *Prunus*, but should be rather κοκκομελέα, which sheweth that *Gaza* was slenderly advised to give the word such a name that a Plumme should beare a seede to be carryed away with the winde, *Pliny* calleth it *Coggygria*, or *Coggyria*, yet some have it *Coccygria*: some also thinke it to be the *Cotinus Pliniy*, and for a distinction betweene it and the *Oleaster*, which is called *Cotinus* also, they call this *Cotinus coriaria Pliniy*, in imitation whereof as it is thought, those that dwell at the toppes of

the *Apennine* hils doe call it *Scotano*, and those at the foote *Rossolo*, of the red colour of the barke, and not of the Dye, as some thinke, because *Pliny* saith, his *Cotinus* is, *ad lineamenta modo conchylij colore insignem*, for this as is before said, giveth a yellow colour. The *Savoyars* call the wood hereof which they loppe and fell for that purpose *Fustet*, and we Fusticke, which all Dyers know is of especiall use with them, both the old wood to give one yellow colour, and the young another. *Matthiolus*, *Anguilara*, *Camerarius*, and *Gesner* in *hortis* call it *Cotinus*, yet *Gesner* also calleth it *Coccigria forte Barba Iovis Plinij*. *Dodonæus Cotinus Coriaria*, *Coggygria* by *Clusius* and others, and of *Cæsalpinus Scotanum vulgo*, as the common people did. The last is liker to be the *Rhus sylvestris* and called by *Lugdunensis*, *Rhus sylvestris altera*, by *Clusius Rhus herba Plinij*, and thinketh it is the *Dryophanon Plinij* also, as *Ruellius* did before him, and *Myrtus nemoralis*, *Cordus* tooke it to be *Elæagnus*, and *Bellonius stirpium cultura*, tooke it to be the *Elæagnus* of *Theophrastus*, and *Lobel* therefore called it *Elæagnus Cordi*, and *Dodonæus Chamælæagnus*, *Lobel* calleth it *Gagel Germanorum*, and *Myrtus Brabantica*, and *Belgarum*, but I may say as well *Myrtus Anglica*, for it is as plentifull with us as with them, but that *Lobel* did not know so much? The *Arabians* call the first *Sumac*, *Adurion*, *Rosbar*, *Sadisticos*, or *Rosaidicos*, the *Italians Rhu*, and *Sumaco*, the *Spaniards Sumach* and *Sumagro*, the *French Sumac*, the *Germanes Gerberbaum*, the *Dutch Sumack* and *Smack*, and we in *English* Sumacke, and red Sumacke, the *French* call the last *Pinceutroyall*, that is Royall Balme: the *Germanes Gagel*, as is before said, and we Gaule and sweete Willow.

*The Vertues.*

Sumacke both leaves and seedes, and the medicines made of them are cooling in the second degree, and drying in the third, the leaves of the first Sumacke have an astringent quality, that they may serve instead of *Acacia*, for those purposes it is used, he decoction of the leaves and seede is singular good for all sorts of fluxes in man or woman, to take them in broth, or in meate or drinke, and to sit in the decoction while it is warme, as the bloody flix, the flux of the stomacke, womens courses, and the whites also, to be drunke or invected by glisters or otherwise, or in bathes, it stayeth the stomacke that is much given to casting, the decoction of the leaves or seede made with vinegar, and a little honey put thereto is good against Gangrens or Cankers, the juyce that is taken out of the dryed leaves by boyling them in water and after they be strayned to boyle them againe with some honey, hath the same properties that *Lycium* hath, the same helpeth the roughnesse of the tongue and throate: the seede likewise boyled in water, and the decoction thereof evapoured to the thicknesse of honey, is more effectuall then the seede it selfe: the decoction of the greene leaves maketh the haire blacke to be washed therewith: the juyce of them dropped into the eares dryeth up the moisture and running of them: the seede beaten and boyled into a pultis and applyed to any inflammation or hot Impostume, cooleth them much, and doth also take away the markes and paines of bruises and blowes, as also the frettings and gallings of the skinne, the same also helpeth the hemorrhoides or piles when they bleede too much, if it be applyed with the fine pouther of Oken coales: it is singular good also to be applyed to ruptures, both inwardly and outwardly, and to stay defluxions of hot and sharpe rheumes into the eyes, and *Damocrates* used it in a medicine with Poppy heads, against destillations from the head, and against want of sleepe: the gum that is found oftentimes issuing out of the tree, is good for hollow teeth, to ease the paines, and the decoction of the seede is good to wash the mouth both to fasten loose teeth, and to heale putrid and rotten gummes. What the *Virginia* Sumacke will performe, I have not knowne any hath made the proofe, but it is probable it might worke some of these effects if any would make the tryall. Both the Myrtle leafed Sumacke and the *Venice* are in a manner as effectuall to all the purposes aforesaid, except that they are a little weaker. The Gaule is by the bitternesse and harshnesse found to be both drying and discussing, and is very effectuall to kill the wormes in the belly or stomacke: it mightily affecteth the braine, causing first perturbations and then sopiting the sences: it is much used to be laid in Wardrobes, Chests, Presses, and the like, to keepe mothes from garments, and woollen cloathes as also to give them a good sent.

---

## CHAP. XLV.

### *Myrtus.* The Myrtle.

Aving spoken of the Gaule in the Chapter before, which some account a kinde of Myrtle both from the forme and sweetenesse, I thinke good to set the stocke of the Myrtles next thereunto, which are many, because although I have shewed you three of them in my former Booke, yet I have not shewed you all the properties they have.

1. *Myrtus latifolia maxima.* The greatest open Laurell Myrtle.

This greatest Myrtle hath great and thicke wooddy branches set with a double row of large leaves yet not so close as the next comming neere unto the smaller leaves of the Bay tree, but of a paler greene colour, abiding alwayes greene and very sweete: this sort saith *Clusius* even in *Spaine* seldome beareth either flowers or fruite, because they pruine it often, being kept in hedges for pleasure.

*Clusius* maketh another sort hereof which differeth little from the former, but in the leaves which are somewhat smaller and thicker, whereas the former are thinner.

2. *Myrtus latifolia exotica.* The strange broad leafed close Myrtle.

This Myrtle groweth higher then the former, and shooteth from the roote store of strong thicke stemmes more plentifully stored with large leaves, yet not fully so large as the first sort, but closer set together that they almost touch one another sometimes in a double row and sometimes in a treble, and very sweete: the flowers are white like unto others but larger, after which commeth the fruite, somewhat longer then in the small sorts, greene at the first, purplish before it be ripe, and blacke when it is full ripe, with many crooked white seedes within them.

3. *Myrtus latifolia vulgaris.* The usuall broad leafed Myrtle.

This usuall broad leafed Myrtle (which I so call because we have this onely in our Country, of all other sorts of broad leafed Myrtles) groweth to be foure or five foote high with us, and in the warme Countries to be a little tree full of branches and leaves, like a small bush, the leaves are somewhat large and great, yet not so large as the last, as

sweete

1. *Myrtus latifolia maxima.*
The greatest open Laurell Myrtle.

2. *Myrtus latifolia exotica,*
The Arange broad leafed close Myrtle.

5. 7. *Myrtus Bætica sylvestris & minor acuto folio.*
The Spanish wild Myrtle and the small poynted Myrtle.

8. *Myrtus domestica minutissimis folijs fructu albo,*
The small white Myrtle,

ſweete as the other, and the flowers white like the reſt, and ſweete likewiſe, the fruite hereof is blacke alſo.

4. *Myrtus angustifolia exotica.*

The ſtrange narrowleafed Myrtle.

This narrow leafed ſort groweth in all parts like unto the ſecond, but that the leafe is ſmaller, narrower, ſmall pointed, and of a darker greene colour, the flowers are alike, and ſo is the fruite blacke alſo, but greater and rounder, having crooked white ſeedes in them, as the others have.

5. *Myrtus Bætica ſylveſtris.*

The *Spaniſh* wild Myrtle.

This wilde Myrtle groweth neither ſo high, nor ſo thicke with leaves, as the former manured ſorts, but have ſlender and brittle branches, with broader leaves then the laſt, ſet more thinly on both ſides then the reſt, and of a darke greene colour: the flowers are like the reſt, and the fruite is round, ſtanding on long footeſtalkes betweene the leaves in good plenty, greene at the firſt, and whitiſh afterwards, and blackiſh being ripe full of ſweetiſh juyce, pleaſant, with ſome aſtriction to the taſte.

6. *Myrtus domeſtica minutiſſimis foliis fructu albo.*

The ſmall white Myrtle.

This white Myrtle groweth reaſonable tall, with ſlender reddiſh branches, thicke buſhing together, being thicke ſet with very ſmall (even the ſmalleſt of any other,) leaves, narroweſt of any, and ſharpe pointed, and ſomewhat darke greene alſo: the flowers are white like the reſt, and ſo is the fruite likewiſe, but of a whitiſh colour, tending to a little bluſh, and ſo abide, not changing blackiſh.

7. *Myrtus minor acuto folio.*

The ſmall and pointed Myrtle.

This ſmall Myrtle riſeth not ſo high as the third, or ordinary broad leafed ſort, but groweth fuller of branches, and thicke ſet with ſmall fine and greene, almoſt ſhining round leaves a little pointed at the ends, abiding alwayes greene, as all the ſorts of Myrtles doe, which and the flowers are ſweete alſo, but grow not plentifully in our Country on the branches, as in warmer places, and beareth blacke berryes, but never in theſe colder climates, howſoever houſed or defended.

8. *Myrtus minor rotundiore folio.* Boxe leafed Myrtle,

This other ſort groweth in all points like the laſt, but that the leaves being as ſmall and freſh, greene, thicke growing, are rounder at the ends, very like unto the ſmall Box leaves, and beareth flowers as ſparingly.

9. *Myrtus flore pleno.* Double flowred Myrtle.

Of the greater kinde of Myrtle, there hath beene of later times one nourſed up in the Gardens of the chiefe Lovers of rarities, with as double flowers as the double Fetherfew, comming forth of a round reddiſh huske, continuing flowring at the leaſt three moneths, and each flower a fortnight, and is not over tender to be kept, yet is not ſo hardy to endure the froſts, as *Cornutus* ſaith, which Maſter *Tradeſcant* can ſufficiently witneſſe, who by a little neglect loſt a good plant overtaken with the froſt.

*The Place* and *Time.*

Myrtles of many ſorts are found generally upon all the Sea coaſts of *Spaine*, *Italy*, and in divers other Countries alſo. The firſt two ſorts *Cluſius* found in *Spaine*, not growing naturally wilde, but in certaine Monaſteries, and private mens Orchards. The third I thinke came out of *Italy*, becauſe it is moſt like to that ſort they ſo call. The fourth he likewiſe found in a Monaſtery, not farre from *Corduba*. The fifth in many places wilde, both of *Spaine* and *Portugall*. And the ſixt in a private noble mans garden in *Portugall*. The two laſt ſave one, are nourſed up moſt frequent in our Land, and better indure therein, with ſome good heede and looking unto: but generally even in the warme Countries they muſt be defended from the cold for feare of danger, as *Virgil* ſheweth in this Verſe *Eclog* 7. *Dum teneras defendo a frigore Myrtos.* and *Ovid* in the like manner ſaith *Metuentem frigora Myrtum*, and yet *Virgil* in another place ſaith, *Amantes frigora Myrtos*: Which how both ſhould be true, I can imagine no other, but that *Virgil* ſpeaketh of the firſt in a cold place, and of the other as they grow in a warme, that the cold place muſt have ſhelter and defence againſt the cold, as it is with us, who give them all the comfort we can: and that they that grow in a warme and hot Countrie muſt have ſhadow, for they love both ſhadow from the heate, and moiſture in the warme Countries. The laſt hath no naturall place aſſigned. They flower in *May*, and the fruite is ripe about *September*.

*The Names.*

It is called in Greeke μυρσίνη and μυῤῥίνη, ſo called a *Myrſine Athenienſi puella amica Palladis a qua curſu & paleſtra, ſuperata, invidia ducta interimit; arbuſcula in demortuæ vicem ſucceſſit, ſemper ut olea Minervæ chara*: but *Pæna* ſaith, *ſic vocatam volunt, propter æmulam Myrrhæ odoris gratiam, in ejus baccis recentibus*: yet when we ſhew you here a *Myrtus ſylveſtris*, as well as *ſativa*, or *domeſtica*, you muſt not underſtand the *Oxymyrſine*, that is *Bruſcus*, which ſome called alſo *Myrtus ſylveſtris* to be it, but as in oppoſition to the tame or manured of the ſame kinde.

9. *Myrtus flore pleno.* Double flowred Myrtle.

kinde. *Dioscorides* maketh mention of both these sorts, and the white one also, although he hath described but one: but some doe much mervaile that *Theophrastus* that doth so often make mention of the Myrtle, yet hath in no place described it. The first sort here set downe is the first *Myrtus* with *Clusius*, called by him *Myrtus Bætica latifolia domestica*, and by *Lobel Myrtus laurea secunda*. The second is called by *Clusius*, *Myrtus Bætica latifolia exotica*. The third is as I take it the *Italica Camerarij*, which *Matthiolus* and others doe describe, and may be the *Conjugula* of *Cato*, which *Pliny* calleth *nostras*, that is *Romana*, and *Lobel Laurea maxima*, and is most likely to be the *nigra* of *Dioscorides*. The fourth is the *Myrtus Bætica angustifolia exotica* of *Clusius*, which *Lobel* calleth *Myrtus exotica Pliny*, and although it have not six order of leaves, as *Pliny* his *exotica*, yet saith *Clusius*, the leaves grow thicke together, that it seemeth to have more then it hath. The fifth *Clusius* calleth *Myrtus Bætica sylvestris*, and is the *Myrti majoris quinta species* of *Lobel*, and *Myrtus sylvestris* of *Matthiolus*. The sixth is the *Myrtus domestica fructu albo* of *Clusius*, which *Bellonius* often remembreth in his Observations, and is the *Myrtus nona angustifolia* by *Lobel*. The two last save one are very likely to be the *Tarentina*, and so *Matthiolus*, and *Clusius* take them to be. *Lobel* calleth them *Myrtus minor vulgaris*, and so others, because as I said they best abide our Northerne Countries. The last is so called by *Cornutus* as it is in the title. The Excressence that is often found growing upon old Myrtle trees, is called *Myrtidanum* and *Myrtadanum* by *Dioscorides*, and *Myrtidanum*. Yet *Pliny* calleth *Myrtidanum*, the wine that is made of Myrtle berryes. There are likewise, saith *Bellonius*, in his Observations, certaine *Coccos*, or red berries, like unto the Chermes berries growing upon the Myrtles in many places of *Turky*, which have in them but one flye or worme, and used as the Chermes to dye withall. The *Arabians* call it *Aes Alas* and *As*, the *Italians Myrto*, and *Mortello*, the *Spaniards Murta*, and *Raiam*, the *French Myrte* and *Menrtre*, other Nations follow the Latine as neere as they can, the Apothecaries and Druggists shops call the berries *Myrtillus*, and we in *English* Myrtle berries.

*The Vertues.*

The Myrtle as *Galen* saith hath contrary qualities in it, for it hath a passing cold earthy quality in it, and a certaine thinne warme essence also, and therefore it powerfully dryeth and bindeth. The dryed leaves are more drying and binding then the fresh, which being beaten and boyled with water, is good to drinke against catarres, falling to any part of the body, and doth helpe also the fluxes of the belly or stomacke, moist ulcers, and fretting or creeping sores, being applyed to the swellings and heate of the cods, the Impostumes of the fundament, and Saint *Anthonies* fire: the decoction of the leaves is good for the resolution of the Arteries and joynts, and their weakenesse to sit in or over the same, as in a bath, and doth helpe to consolidate broken bones or out of joynt, that will hardly be cured, it helpeth the sorenesse of the nayles, and that rising of the skin about them, if the pouther of the dryed leaves be cast thereon: the juyce of the leaves is of the same effects, whether out of the fresh leaves, or taken from the dry, by infusing red Wine on them, and is safely used where there is neede of any binding medicine, or to heale the ulcers of the mouth or privy parts: the same also helpeth watering eyes or those that beginne to have a filme or skin to grow that will take away the sight. The seede is good for the tremblings and passions of the heart, and to helpe those that spit blood, or have the bloody flixe, it stayeth also womens immoderate courses, and the whites also, it helpeth the sting of Scorpions, and the bitings of venemous creatures, and of the Spider *Phalangium*, and the danger of Mushromes: being drunke in Wine, it helpeth a stinking breath, and amendeth that which is not sweete, the same also heated with Wine healeth old ulcers, that are hard to cure: it helpeth the diseases of the bladder, and provoketh urine, it also bindeth the belly, and stayeth the fluxe of humours, the blanes, wheales, and other breakings out in the skinne: the decoction of them, is good for women to sit in or over, that are troubled with the falling downe of the mother, and is good also for the falling downe of the fundament, and the piles. The Excressence called *Myrtidanum*, is of greater force to dry and binde then either leafe, juyce, or seede: the juyce condensate of Myrtles is commended by *Matthiolus* for a better substitute, for *Acacia*, then the juyce of Sloes, which hath not that aromaticall sent, and strengthning quality that the Myrtle hath.

---

## CHAP. XLVI.

*Vitis Idæa sive Myrtillus Germanica vel Vaccinium frutex.* Whortle berries.

THere are divers sorts of these low shrubs, which must all goe under the name of Whorts or Whortle berries, although there is much difference betweene them.

1. *Vaccinia nigra vulgaria.* Blacke Whortes or Bill berries.

This small bush creepeth along upon the ground, scarce rising halfe a yard high; with divers small darke greene leaves set on the greene branches, which it spreadeth abroad on both sides, but not alwaies one against another, somewhat like unto the smaller Myrtle leaves, but not so hard, and a little dented about the edges: at the foote of the leaves come forth small hollow pale blush coloured flowers, the brimmes ending in five points, with a reddish thred in the middle, which passe into small round berries of the bignesse and colour of Iuniper berryes, but full of a purple sweetish sharpe or sowre juyce, which doth give a sad purplish colour to their hands and lips that eate and handle them, especially if they breake them; containing within them diver small seed: the roote groweth aslope under ground, shooting forth in sundry places as it creepeth: this looseth the leaves in Winter.

2. *Vaccinia nigra fructu majore.* The greater Bill berry.

This other Bill berry groweth greater and higher then the former, whose lower part of the branches are of an ash colour, but the upper part, greene and sometimes reddish, the leaves are somewhat rounder pointed, the flowers and berryes, are like the other in all things, save that they are larger, but of the same colour being ripe, and of a more pleasant sweete and lesse sharpe taste: the roote creepeth in the same manner.

3. *Vaccinia nigra Pannonica.* *Hungarian* Blacke Whorts.

This *Hungarian* Whort hath tough slender stalkes, lying for the most part, on the ground, and there taking

roote

1. *Vaccinia nigra vulgaria.*
Blacke Whorts or Bill berries.

2. *Vaccinia nigra fructu majore.*
The great Bill berry.

3. *Vaccinia nigra Pannonica.*
Hungarian Blacke Whortes.

4. *Vaccinia rubra Buxeis folijs.*
Red Whortes with Boxe leaves.

6. *Vva Vrsi Galini Clusij.*
The Spanish red Whort.

7. *Vitis Idæa tertia Clusij.*
The French Hony sweete Whorts.

8. *Vitis Idea Cretica elatior*
The taller red Whorts of Candy.

9. *Vitis Idæa Cretica humilior.*
The lower Candy red Whorts.

rootē againe in some placēs, with many branchēs, scarse raising up themselvēs above the Mosse, among which it groweth, having sundry long and somewhat narrow leaves, upon long footestalkes set without order on them, greene above and paler underneath, and a little nicked about the edges, with a few soft haires on them also, and of a very astringent taste: the flowers come forth at the end of the last yeares shootes or branches, which were not observed, but there stood blacke round berries, as bigge almost as Cherries, upon long footestalkes, hanging downe when they were ripe but reddish before, full of a not unpleasant juyce, conteining within them no stones like

like Cherries but five seedes for the most part, being flat and white: the roote is wooddy with some fibres joyned thereto: this holdeth the greene leaves all the Winter.

4. *Vaccinia rubra buxeis foliis.* Red whorts with Boxe leaves.

This red Whort riseth up like unto the great blacke Whort, having sundry harder leaves like unto the Boxetree leaves, greene and round pointed standing on the severall branches at the toppes whereof onely, and not from the sides, as in the former come forth divers round and somewhat long hollow flowers, of a pale red colour, after which succeede round reddish sappy berryes, when they are ripe, of an acide and astringent taste: the roote runneth in the ground like the blacke: the leaves hereof fall not away in Winter.

5. *Vaccinia rubra longioribus foliis.* Red Whorts with longer leaves.

This other red Whorte is like a low creeping shrub, but groweth somewhat thicker and greater then the former red, the leaves whereof are longer narrower and sharper pointed then it, and growing reddish toward Autume, but yet abiding on the branches like the former, and not falling of in Winter: the flowers are like the other, and so is the fruite, but not sappy, or with juyce therein, but dry and saplesse, and without any manifest taste.

6. *Uva ursi Galeni Clusio.* The *Spanish* red Whort.

This *Spanish* Whort likewise differeth not much from the former red sorts, having slender flexible stalkes and branches, about a foote long, lying on the ground, covered with a reddish barke, somewhat like unto the tender branches of the Strawberry tree, having sundry leaves set thereon, neere resembling the Strawberry tree leaves but lesser, being thicke and sappy but not hairy at all, and somewhat bitter with the astringent taste: at the ends of the branches grow divers bottle like or hollow round flowers, growing in clusters of the same whirish blush colour that they are of, after which follow round red berries, like unto small Cherryes, but of an acide taste: the leaves hereof likewise abide on the stalkes and fall not away in Winter.

7. *Vitis Idæa tertia Clusij.* The *French* honey sweete Whortes.

This riseth higher then any of the former, to be foure or five cubits high, with sundry thicke smooth wooddy stemmes from the roote, the lower parts being somewhat rough and covered with a blackish barke, the upper branches being greene, stored with many leaves thereon, set without order, which are somewhat long with the roundnesse, and a little dented about the edges, of a sad greene colour above and very hoary underneath: at the joynts with the leaves come forth many white flowers, consisting of five leaves a peece, after which come small round berries somewhat bigger then Hawthorne berries, and blacke when they are ripe, having a small crowne as it were of five small points which were the flowers, sticking at their toppes, and being sappy of a sweetish taste like honey, with sundry blackish seede within them.

8. *Vitis Idæa Cretica elatior.* The taller red Whortes of *Candy*.

This small shrubby plant sending forth sundry slender wooddy blacke shootes from the roote, the wood being hard and white without any sent, but somewhat heating the tongue on the tasting, parted into divers branches, furnished at the joynts, by unequall spaces, sometimes with single leaves, but usually with two, and sometimes with three or foure together, which are somewhat hard and almost round, dented also a little about the edges, being somewhat like unto Holly, but nothing so hard or prickely, of a sad greene colour on the upper side and grayish the lower, at the ends of the branches, and at the joynts also with the leaves come forth sundry white Cherrylike flowers, each on a long footestalke, and after them small round and somewhat long reddish fruite, of a pleasant taste, of the bignesse of a Beane, having a freezy or woolly crowne at the toppes, and being dry turneth blacke and hard.

9. *Vitis Idea Cretica humilior.* The lower *Candy* red Whorts.

This other *Candiot* groweth much lower, fuller of sprigges slenderer also and shorter whereon at unordinary spaces, stand unordinary leaves, three or foure sometimes together, being almost round like unto the last, but lesser softer, smoother and not so much dented about the edges, neyther yet of so sad a greene colour on the upperside, nor so gray on the under, at the joynts likewise with the leaves come forth long stalkes, with many the like white blossomes in a cluster, turning into smaller berries, of a darke red colour, and a little downy at the head, somewhat like unto Mirtle berries, which are familiarly eaten by the Shepheards, and others of the Country.

*The Place* and *Time.*

The first groweth in many heathes, woods and barren hilly places of this Land, as *Hampsteede Heath*, *Fincheley*, and Saint *Iohns* wood, not farre from *London*, and in sundry other places. The first red sort in the North parts, as *Lancashire*, and *Yorkeshire*, on the hills, &c. The rest grow in *Hungaria*, *Bavaria*, and *Germany*, and in other Countries also. The sixth *Clusius* found in *Spaine*, and the branches and berries were shewed me by *Boel*, that brought them out of *Spaine*. The seventh groweth as *Lobel* saith on every of the hils in *Provence* of *France*, and *Clusius* on the hils nigh *Vienna*. The two last in *Candy*. They all flower in *March* and *Aprill*, and the fruite of the blacke is ripe in *Inne* and *Iuly*, the other later.

*The Names.*

The first blacke sorts are taken generally by the best later Writers, to be the ἀμπελος πυξίδης of *Theophrastus*, that is, *Vitis ex parte Idæ, quam vocant Phalacras*, but *Pliny* falsly put in *Alexandrina* instead of *Idæa*, in Latine by them *Vitis Idæa Theophrasti*, and because all the rest have a resemblance thereunto, they are all called *Vites Idæa*, likewise, with their severall distinctions, as you shall presently heare: they are many of them also called *Vaccinia*, by divers, thinking the black sort to be the *Vaccinia nigra* of *Virgil*, & by the transposition of a letter *Baccinia nigra parva quasi bacca*; but that errour is exploded by many good Authours, that shew *Virgil* putteth his *Vaccinia* among flowers, and not fruites; for as he saith, *Et sunt Violæ nigræ, & Vaccinia nigra*, intending the colours were both alike, as a kinde of *Hyacinth*, which he might meane is as the Violet flower. *Vitruvius* and *Pliny* indeede have a *Vaccinium* which giveth a purple dye to servants or others garments, which may very wel be this, for such a purple colour will the juyce hereof give, if it be rightly ordered. It is also called *Myrtillus*, and by some *Myrtillus Germanica*, because the Physitions and Apothecaries in *Germany* and those parts, tooke them to be true Mirtle berries, and so used them untill they were shewed their errour, and since have forsaken it, as we have done also. *Gesner* also in *hortis* sheweth, that some did take the *Vitis Idæa*, to be that Vine that beareth Currans, but saith he, that noble Vine groweth not on so high or snowy mountaines, but rather in the Planes and open hils, and ordered by the industry of men. The first *Tragus* calleth *Myrtillus exiguus*, and so doe *Matthiolus* and *Lugdunensis*. *Do-*

*donæus*

*donæus* and *Lobel*, called it *Vaccinia nigra*, *Anguilara*, *radix Idæa fructu nigro*, *Camerarius*, *Gesner* and *Clusius*, *Vitis Idæa vulgaris baccis nigris*. *Cæsalpinus Bagolæ primum genus*. The second is called by *Tragus*, *Myrtillus grandis*, and is the *Vitis Idæa major* of *Thalius*, the *Vitis Idæa secunda sive altera* of *Clusius*, and the *Vitis foliis subrotundis exalbidis*, although he hath transposed some of these titles to his second, which is my third whereof onely *Clusius* maketh mention and calleth it his first, and *Gerard*, *Vaccinia Pannonica*, and *Bauhinus* calleth *Vitis Idæa foliis oblongis albicantibus*. The fourth is called *Vaccinia rubra*, and *Vitis Idæa rubra*, by all writers thereof: *Camerarius* and *Thalius* say that some tooke it to be *Rhus minor Pliny*; and *Clusius Vitis Idæa buxeis foliis*, and *Anguilara Radix Idæa fructu rubro*, as he did the blacke before, *Radix Idæa fructu nigro*, and *Lugdunensis* doth thinke that this is most properly the *Radix Idæa* of *Dioscorides*. The fifth is mentioned onely by *Camerarius* in *horto*, who calleth it *Vitis Idæa rubra Bavarica*. The sixth is referred by *Clusius* to the ἀρκτοσταφυλος of *Galen* in his seventh Booke, *de composit. med. secundum locos. cap.* 4. and thereupon he called it *Uva ursi Galeni*, *Bauhinus* refereth it to the *Vitis Idæa*, making it his sixth and calleth it *Idæa radix Dioscoridis* also. The seventh is called by *Clusius Vitis Idæa tertia*, not thinking his former to be so worthy of that name, *Lobel* saith the *French* call it *Amelanchier*, and doubteth if it be not that shrub which they call *Alisier*, *Bellonius* saith, that their *Melanchier* is called in *Candy Agriomelea* and *Codomalo*, but I thinke he is deceived, that having blacke, and this red fruite: *Gesner* in his Epistles, as *Clusius* saith (if he meant this plant) giveth it divers names, as *Myrtomalis*, *Petromelis*, *Pyrus Cervina*, and *Pyraster Idæa*. *Dalechampius* taking it to be *Cotonaster Gesneri*, calleth it *Epimelis altera*, but giveth it red berries, which therefore I suppose may be rather one of the two last. The two last are mentioned by *Alpinus*, in his Booke of Exoticke plants, by the name of *Cerasus*, and *Chamæcerasus Idæa Cretica*, thinking the former most neerely to be the *Cerasus Idæa Theophrasti*. The *Italians* did use to call the first *Mirtillo*, but now *Vite Idæa*, according to the Latine, the *French Airelle* and *Aurelle*, the *Germanes Heidelbeer*, the *Dutch Crake besien*, and we Whorts or Whortle berryes, and Bill berries with us about *London*.

*The Vertues.*

The Bill berries doe coole in the second degree, and doe a little binde and dry withall: they are therefore good in hot agues, and to coole the heat of the stomacke and liver, and doe somewhat binde the belly, and stay castings, and loathings, but if that they be eaten by those that have a weake or a cold stomacke, they will much offend and trouble it saith *Camerarius*, and therefore the juyce of the berries being made into a Syrupe, or the pulpe of them made into a conserve with Sugar, will be more familiar to such, and helpe those paines, the cold fruite procured, and is good for all the purposes aforesaid, as also for those that are troubled with an old cough, or with an ulcer in the Lungs or other disease thereof: with the juyce of the berries Painters to colour paper or cards, doe make a kinde of purple blew colour. putting thereto some Allome and Galles, whereby they can make it lighter or sadder as they please. And some poore folkes as *Tragus* sheweth, doe take a potfull of the juyce strained, whereunto an ounce of Allome, foure spoonefuls of good Wine vinegar, and a quarter of an ounce of the waste of the copper forgings, being put together, and boyled all together, into this liquor while it is reasonable, but not too hot, they put their cloth, wooll, thred or yarne therein, letting it lye for a good while, which being taken out and hung up to dry, and afterwards washed with cold water will have the like *Turkie* blew colour, and if they would have it sadder, they will put thereto in the boyling an ounce of broken Gaules: *Gerard* saith, that hee hath made of the juyce of the red berries, an excelleut crimson colour, by putting a little Allome thereto: the red Whorts are taken to be more binding the belly, womens courses, spitting of blood, and any other fluxe of blood or humours, to be used as well outwardly, as inwardly.

## CHAP. XLVII.

### *Iovis barba frutex.* The silver Bush.

THis beautifull fine bush groweth to the height of a man, with a number of slender branches, thicke bushing out on all sides, whereon grow long winged leaves made of many small ones like Lentill leaves, but narrower, each set against other, with an odde one at the end, of a faire greene colour on the upperside, and of a silver white shining colour underneath, the young leaves being also of the same colour: at the ends of the branch standeth large umbels of yellow flowers, made after the fashion of broome flowers, set in grayish huskes, like the heads of the three leafed grasse, after which come small narrow short pods, soft and grayish likewise, with two or three small round, and somewhat long blackish gray seede in them: the roote is hard and wooddy: this is very tender, not induring our Winters, although housed, nor any where in our Country, but in a warme stove, where the fire may preserve it from the cold, which it will not abide early or late: that is, it must be housed betimes, and not set abroad too earely.

*The Place* and *Time.*

It groweth on the hill *Setius*, called *Cap de sette* of the *French*, not farre from *Agatha*, by *Mompelier*, as also upon *Mons niger*, not farre from *Ligorne* in *Tuscany*. And flowreth in *May* in the naturall places, the seede being ripe in *July*.

*The Names.*

I finde none of our moderne writers, to have made mention hereof, before *Anguilara* (who found it on the blacke hill

*Iovis barba frutex*, The Silver Bush.

by

by *Ligourne*, as is before said, and in his first kinde of *Barba Iovis*) since *Pliny*, who speaketh thereof *lib.16.c.18.* that it shunned the waters, and was called *Iovis Barba*, and was fit to make hedges and border up beds, to be framed into any worke in a Garden, and *Cæsalpinus* since him. *Camerarius* onely nameth it, and so doth *Clusius*, but *Lugdunensis* describeth it, and lastly *Bauhinus* in his *Pinax*, and all of them by the name of *Barba Iovis*, and yet the *Sedum majus*, great Houseleeke is also called by that name, but to put a distinction betweene them, this is called *Barba Iovis arbor* or *frutex*.

*The Vertues.*

There is nothing extant of any Physicall property, whereunto this plant may be applyed, and therefore thus much shall be sufficient untill the Vertues be better knowne.

## CHAP. XLVIII.

### *Periclymenum sive Caprifolium.* Woodbind or Hony Suckles.

WE have divers sorts of plants under the name of *Periclymenum*, some that are winding about whatsoever standeth next them, and for the most part knowne throughout the Land, others are strangers, or not so well knowne: there are likewise divers that winde not, but stand upright, which I would separate in sunder as *Bauhinus* doth, but not make them kindes of bastard Cherries as hee doth, but joyne them in name, although I disjoyne them by Chapters, both because they have notable differences, and that I might not trouble you or my selfe with too many sorts in one Chapter.

1. *Periclymenum sive Caprifolium vulgare.* Our ordinary Woodbinde.

Our common Woodbind is well knowne to grow up with a wooddy stalke and branches, winding themselves, yet without claspers, so stricktly unto whatsoever branch of any other tree, that it leaveth an impression therein of the winding, set with sundry leaves by couples, which are somewhat broad and long, round pointed, and of a whitish greene colour above, and more whitish underneath: at the toppes of the branches come forth many long and hollow whitish and yellow flowers, laid open before, with many small threds sticking in the middle of them, of a fine sweete sent: after which succeede small bunches of red berries, wherein is contained small hard seede: the roote is wooddy with many fibres.

2. *Periclymenum sive Caprifolium Germanicum flore tubello.* The *Germane* red Honisuckle.

This *Germane* sort groweth higher and larger spread then the former, but ramping in the like manner, with the like leaves, but somewhat larger as the flowers are also, being red in the bud before they be blowne open, and continuing reddish on the outside, the bottomes of the flowers being wholly white on the inside.

3. *Periclymenum perfoliatum sive Italicum.* Double Woodbinde or Honisuckles.

The double Hony suckle groweth in the same manner as the other, but spreadeth more and farther, with whitish ramping branches, and such manner of whitish greene leaves set on both sides of the branches up to the tops,

1. *Periclymenum sive Caprifolium vulgare.* Woodbinde or Honysuckles.

3. *Periclymenum perfoliatum sive Italicum.* The double Hony suckle.

where

where it beareth many flowers, at two or three ſeverall diſtances one above another, with two round leaves under them, at the joynts joyned ſo cloſe together, that they ſeeme like ſawſers to hold the flowers, which ſtand in the middle, and are of the ſame faſhion and colour with the former, that is of a whitiſh yellow colour, with open mouthes, daſht over with a light ſhew of purple, with threds within them likewiſe, and as ſweete: this beareth ſeede likewiſe, but not ſo many together.

4. *Chamæperi lymenum.*
Dwarfe Hony ſuckle.

This Dwarfe Hony ſuckle h th a creeping roote, running here and there underground, and ſhooting up ſtalkes with ſundry leaves ſet by couples at the joynts, full of veines, and with five ribs running all the lenth of the leafe to the end, which is pointed, ſmooth and not dented about the edges, from the toppes of the ſtalkes grow forth two branches, with foure or five ſuch like leaves as grow below, and from betweene the foote of them commeth a ſmall tuft of flowers, (which were not obſerved) and after them many red berries ſet in a bunch or knob together, like the Mulberry, but longer, and therefore I thinke it ſhould rather pertaine to the family of the *Chamæmori*, but that, as *Cluſius* to ſhew, not only his love to Doctor *Penny*, in letting it paſſe by his name, but alſo his judgement thereof by the name, ſo I, untill I can have better knowledge of the Plant, muſt let it ſo paſſe, but with my caution.

4. *Chamæperic'ymenum.*
The Dwarfe Hony ſuckle.

*The Place* and *Time.*

The firſt groweth every where in this Land, in the hedges abundantly. The ſecond in *Germany*. The third in *Italy*, *Spaine*, *Provence* of *France*, *&c.* Both it and the ſecond are onely kept in our Gardens, or Orchards, or ſet againſt an houſe ſide to runne about the Windowes, where they keepe the roomes coole, and make a goodly ſhew without. The laſt was found by Doctor *Penny*, as *Cluſius* ſaith, by *Dantzicke*, who gave him both the figure and the deſcription as it is here expreſſed. The firſt is in flower in *Iune*, and the fruite is ripe in *Auguſt*. The ſecond and third are earlier, both for the flower and fruite, yet we never ſaw fruite of the ſecond to follow any of the flowers.

*The Names.*

It is called in Greeke περικλύμενον, but the Greekes in theſe dayes, περιπλόκὰς, in Latine *Periclymenum* alſo, and *Caprifolium*, but *Pliny* miſtaking the word *Periclymenum*, ſetteth downe the properties of *Clymenum* for it, with ſome *Matriſſylva*, *Volucrum majus*, and *Lilium inter ſpinas*, and *Vinciboſcum* by *Cæſalpinus*, according as his *Italians* called it. The firſt and third are called by all Authours that have written of them, either *Periclymenum* or *Caprifolium*, ſome entitle the firſt *Germanicum*, and ſome *vulgare Septentrionalium*, but the ſecond is more rightly termed *Germanicum*, becauſe I thinke no Country h th it naturally but that. The third is *Perfoliatum alterum*, or *grandius & Italicum*. But the laſt was firſt ſet out by *Cluſius*, and from him *Tabermontanus*, *Gerard*, *Bauhinus*, and my ſelfe have it. The *Italians* call it *Vinciboſco*, the *Spaniards Madreſelua*, the *French Chenrefneille*, the *Germanes Geyſſbladt*, and *Speckgilgen*, the *Dutch Gheytenbladt*, and *Memmekens*, and we in *Engliſh* Wood binde, and Honyſuckle.

*The Vertues.*

We in our Land have by tradition continued ſo long in this errour to uſe the leaves, and flowers, in all gargles, and lotions for inflammations in the mouth, or the ſore privy parts of man or woman, that I thinke the cuſtome is growne too ſtrong by time for me with a few words to ſhew the inconvenience, that it may be reformed, for they are neither cooling nor binding, as they are taken to be: but are of a clenſing, reſolving, conſuming, and digeſting quality, as Hyſſope, O iganum, and Winter Savoury are, that with Figges and Licoris, are effectuall to expectorate flegme from the cheſt and lungs, wherewith they are filled: and that it is not fit to be uſed in inflammations the very taſte of the herbe holding a leafe in ones mouth will declare, by the burning heate will be felt therein, and as *Dioſcorides* and *Galen* ſay, that the decoction thereof being drunke ſixe dayes together, will render the u ine as blood: although at the firſt they will but provoke urine onely, the fruite and leaves as well as the flowers, are of one effect: but the flowers and leaves are of more uſe then the ſeede, which is ſaid to conſume the ſpleene, and to pr ture a womans ſpeedy delivery, but whereas it is ſaid to bring barrenneſſe to men that uſe it, it cannot properly be ſaid of men, but of women to be barren, and of men to be unable to generation, or their ſeede unprofitable upon ſundry cauſes: the leaves or flowers in pouther or the diſtilled water of them, is much commended to clenſe and dry up foule and moiſt ulcers, and to clenſe the face and skinne from morphew, ſunburne, freckles, and other diſcolourings of the skinne. The oyle wherein the flowers have beene infuſed and ſunned, is good againſt cramps, convulſions of the ſinues, and palſies, and any other benumming cold griefe. The double Honyſuckle may ſafely be uſed to all theſe purpoſes, when the other is not at hand.

## CHAP. XLIX.

*Periclymenum rectum.* Vpright Woodbinde or Hony ſuckle.

OF this kinde of *Periclymenum*, there are three or foure ſorts, as you ſhall preſently heare.

1. *Periclymenum rectum fructu rubro.* Red berryed upright Honyſuckle.

The divers ſtalkes of this Hony ſuckle, are ſomewhat ſtraight and upright, about three or foure foote high, at the leaſt, divided and ſpread into divers branches, covered with a very thinne whitiſh barke: the leaves ſtand by couples on the branches and two likewiſe at every joynt, which are of a whitiſh greene colour, ſmooth, and leſſer then thoſe of the former winding Woodbindes: the flowers alſo ſtand by couples at the end of ſhort ſtalkes, that come forth from the joynts with the leaves, and are much ſmaller then the other, and never opening or ſpreading much, of a pale whitiſh colour, after which come two red berries, long with the roundneſſe, both of a bigneſſe in the naturall places, and in ſome open places, and ſeldome ſo with us, for one is uſually withered and never commeth to perfection.

2. *Periclymenum rectum fructu nigro.* Blacke berried upright Honyſuckle.

This groweth not ſo high as the firſt, nor ſpreadeth ſo much but groweth greater in the ſtemme and more upright, whoſe barke is not ſo white: the leaves grow in the ſame manner, but are ſomewhat longer and dented about the edges, the flowers ſtand upon ſmall ſtalkes, as in the former, two uſually together, yet ſometimes but one, of a more purpliſh colour, and ſomewhat leſſer, unto whom ſucceed blacke berries, full of juyce, of no unpleaſant taſte: the roote in both are hard and wooddy.

3. *Periclymeno rectum fructu cæruleo.* Blew berryed upright Honyſuckles.

This is alſo a low ſhrubbe riſing not much higher then the laſt, the ſtemme being greater and covered with a rugged blackiſh barke with divers ſmall branches thereon, the youngeſt being reddiſh at the firſt, and hoary withall: the leaves ſtand by couples as in the reſt, ſomewhat like unto the firſt, of a drying and bitter taſte, the flowers grow by couples, ſmall and pale of colour, as the firſt, after which commeth but one berry uſually, ſomewhat long and round, of a blewiſh colour with a ſweete and little tart juyce within them, colouring the hands red that handle them, and have within them many flat ſeede.

4. *Periclymenum rectum fructu rubro ſingulari majore.* The greater upright Honyſuckle.

The leaves hereof are greater then any of the former, and pointed at the ends, ſet in the ſame manner by couples, on the low ſtalkes, that are not above a cubit high, and they are harder in handling, greene above and gray underneath: the flowers ſtand by couples as in the reſt, and are of a purpliſh white colour, or ſomewhat deeper ſometimes but unto them ſucceede but one berry, the biggeſt of them all even as large as a cherry, red, ſappy, and tranſparent, having two markes at the top, where the flowers grew, but containing within it but one ſeede.

1. *Periclymenum rectum fructu rubro.*
Red berryed upright Honyſuckle.

2. *Periclymenum rectum fructu nigro.*
Blacke berryed upright Honyſuckle.

The

3. *Periclymenum rectum fructu cæruleo.*
Blew berryed Honysuckle.

4. *Periclymenum rectum fructu rubro singulari majore.*
The greater red upright Honysuckle.

*The Place* and *Time.*

All these sorts were found by *Clusius* in *Germany*, *Austria*, and *Syria*, and some on the *Pyrenean* hils, and in *Savoy*, the most of them are kept in our Gardens, they flower in *May*, and the fruite is ripe in *August*.

*The Names.*

Some have called these shrubs by the name of *Xylosteum quasi Lignum osseum ob duritiem*, for they have not beene knowne to the ancient Writers, as it is supposed, but found out by the moderne, and for the resemblance of the flowers, in likenesse although not in bignesse, unto Honysuckles, and that the shrub groweth upright, not leaning or winding as the former kindes doe, they have given them the name of *Periclymenum stans* or *rectum*, as the fittest Epithite to demonstrate them, and each with distinctions one from another, as is fittest. The first is the *Periclymenum Allobrogum* of *Lobel*, and *Periclymenum rectum fructu rubro*, and the first with *Clusius*, and *Xylosteum*, with *Dodonæus*, *Camerarius*, and *Thalius*: *Gesner in hortis* calleth it *Periclymeno cognatus frutex*, and *Tragus*, and *Lonicerus* in the infancy of Herbarisme, not knowing whereunto well to referre them, called it *Halimus*. The second is the second *Periclymenum rectum* of *Clusius*, and so is the third here, his third in his History of Plants. The last is *Clusius* his fourth *Periclymenum rectum*, which *Gesner* at the end of *Cordus*, his history of Plants, calleth *Chamecerasus montana*, and *Lobel Chamæcerasus Alpigena*, *Dodonæus* and *Eystetensis Xylosteum alterum*, *Lugdunensis* taketh it to be the *Ficus Idæa Theophrasti. lib. 3. c. 17.* and calleth it *Ficus Idæa nostras vulgo Frangula*, but *Clusius* saith, he cannot consent to that opinion, nor that it should be *Pliny* his *Ficus Idæa* neither, *Clusius* saith, that they of *Austria* and *Styria* call the first *Hunds kirschen*, and *Bein holtz*, and the three first sorts *Hunds beer*, and we according to the Latine name, upright Honysuckle. *Bauhinus* calleth all these sorts by the name of *Chamæcerasus*, whereof many doe much marvell, seeing the fashion of flowers declare plainely unto what stocke of right they are to be referred.

*The Vertues.*

There is no one that hath shewed these, that hath heard of any property of any of these berries or the shrubs, have in Physicke, but those that are pleasant are eaten oftentimes, and the third sort is much sought after, by the people where it groweth, to serve the Dyers use.

## CHAP. L.

*Gelseminum sive Iasminum.* The Iasminē or Gelsemine.

*Serapio* hath exhibited unto us in his workes, three sorts of Iasmines, with white, blew, and yellow flowers, whom *Tabermontanus* and others doe follow, although without all knowledge of them: divers others much doubting the truth of the blew and yellow, have thought none such to be in *rerum natura*, but time and industry, the disclosers of hidden secrets, have brought them to light, yet very lately, and scarse knowne to our world, or therein but to a few; the true yellow I will shew you in this Chapter, with divers other rare ones, some true, and some that are received for Iasmines, with divers others, and in the next, that yellow Iasmine, which formerly was taken for the right, but farre differing therefrom, saving onely in the forme of the flowers, and in the next Chapter unto that, the true sort of *Serapio*, his blew Iasmine, as I verily suppose, yet because the growing thereof is not answerable to the Iaspines, but more correspondent to the *Lilac*, besides the *Persian* name whereby it came, although many of the leaves thereof resemble a Iasmine, I have placed it there, not without reason as I take it.

1. *Gelseminum vel Iasminum album vulgare.* The ordinary white Iasmine.

The ordinary white Iasmine hath sundry very long shootes from the rootes, sometimes twelve, yea twenty foote high: divided in many branches, covered with a darke grayish barke, the younger branches being greene with a white pith within like the Elder, whereon are set at severall places, long winged darke greene leaves, made of many small and pointed leaves, and the largest at the end, and longest pointed: at the toppes of the young branches, stand divers flowers in a tuft together, each on a long greene stalke, which sustaineth a small long hollow truncke, ending in five white leaves, pointed and smelling very strong and sweete, which fall away without bearing any fruite in our Country, but in the hotter where it is naturall, it beareth a flat seede like a *Lupine*: the roote spreadeth much and farre in the ground, and giveth many suckers.

2. *Gelseminum vel Iasminum Catalonicum simplex.* The single Spanish Iasmine.

This Spanish Iasmine groweth lower then the former by much, but hath leaves and flowers growing in the same manner, and differeth from it onely in the leaves, being somewhat broader, shorter, and thicker, and in the flowers which are larger, and purplish on the outside, before they be open, and white with purplish edges, when they are blowen open, exceeding sweete of smell more then the former.

3. *Gelseminum vel Iasminum Catalonium multiplex.* The double Spanish Iasmine.

This kinde of Spanish Iasmine groweth very like but lesser then the single kind shooting forth such like leaves, but of a fresher greene colour: the flowers likewise stand at the toppes of the branches, many together, but the hollow t unckes are shorter by the halfe ending in five or six leaves laid open like a starre, within which rise three

1. *Gelseminum vel Iasminum album vulgare.* The ordinary white Iasmine.

2. *Gelseminum vel Iasminum Catalonicum simplex.* The single Spanish Iasmine.

or five dayes, yet withering upon the ſtalkes fall not away, but after many dayes ſo abiding, another flower will breake forth of the ſame trunke ſometimes: this hath a quicker ſent then the other.

4. *Gelſeminum ſive Iaſminum Indicum flavum odoratiſſimum.* The Indian moſt ſweete yellow Iaſmine.

This rare Iaſmine riſeth in the warme Countries to be two or three cubits high, the barke whereof is ſmooth, and as red or purple as the Flower-gentle, ſpreading forth branches on all ſides even from the loweſt almoſt, and they againe divided into other leſſer ones, bearing at ſundry places, without order in ſome places, three leaves, in ſome five on a ſtalke, of a very ſad or deepe ſhining greene colour, not dented at all about the edges, nor falling away in Winter, each part whereof is ſomewhat like the leafe of the Pomgarnet tree, but harder and thicker, the flowers grow in the ſame manner at the toppes of the branches, and in tufts, formed very like unto thoſe of the Spaniſh Iaſmine, but ſomewhat leſſer, yet abiding longer, and of a faire gold yellow colour, and exceeding ſweete, after which ſucceed ſmall round heads leſſer then Ollives, greene at the firſt, and blackiſh blew being ripe, cleere, ſhining alſo like a grape, ſtanding ſingly, and ſometimes double upon a ſtalke including certaine blackiſh long ſeed like Peare kernels. This plant is more eaſie to be propagated, either by ſuckers or layers, but is very tender to keepe, not abiding either the leaſt of Winters breath nor yet the cold Autumne dewes, but much delighteth in warmth and moiſture, yet neither enduring much raine or watering, to fall on his leaves or flowers, which will change the flowers paler, and the green leaves yellower, and therefore muſt have the moiſture diſtilled at the rootes. This holdeth the greene leaves in the Winter.

4, 5. *Gelſeminum ſive Iaſminum Indicum flavum odoratiſſimum, & luteum Virginianum odoratum ſcandens ſemper virens.*
The moſt ſweete yellow Indian Iaſmine. And the ſweete yellow climing yellow Iaſmine of Virginia.

5. *Gelſeminum ſive Iaſminum luteum odoratum Virginianum ſcandens & ſemper virens.*
The ſweete yellow climing *Virginian* Iaſmine.

This *Virginian* Iaſmine hath a pretty bigge wooddy ſtocke next to the ground, from whence riſe ſundry hard ſtalkes, dividing it ſelfe into many branches, ſpreading very farre upon the trees, or any thing ſtandeth next to it, whereon are ſet at ſeverall ſmall diſtances, two pretty large Mirtle-like ſmooth leaves, but placed on contrary ſides, each above other, as they are diſpoſed in the double *Syringa Arabica*, or Pipe-tree: the flowers ſtand three or foure together, at the ends of the branches, ſomewhat like unto the former Iaſmines, with a long hollow trunke, ending in five points, but not laid open into leaves like them, of a yellow colour, ſmelling very ſweete, after which follow ſmall, ſomewhat flat and long ſmooth yellow pods, parted in the middle all the length, full of ſmall flat browniſh ſeedes, winged as it were or skinny at the one end, and piled cloſe one upon another in each ſide of the pod.

*The Place* and *Time.*

The three firſt ſorts have beene brought, as it is thought out of *Syria* into *Spaine*, where they thrive paſſing well. The firſt ſort, which they account to be wilde, ſerveth to graft the other two upon, that they may grow and thrive the better; we keepe the ſecond with much care and proviſion, being more tender then the firſt, which is growing in many places of the Land, in private perſons gardens: but the third, I have not heard that it hath beene as yet brought unto us, it being as yet more rare, and as tender to keepe, if not more then the ſecond. The fourth is held doubtfull whether it came from the Eaſt Indies, *China*, or *Iapan*, or the Weſt Indies, for divers doe ſuppoſe the one and the other. The fifth groweth in *Virginia*, as Maſter *Tradeſcant*, who ſaw it there doth affirme, and from him I have a plant riſen of the ſeede. They all flower late, and none of them beare any ſeede with us.

*The Names.*

The *Arabians* call the *Iaſmine Zambach*, and *Sambach*, and *Iaſemin* as it is thought, from the Greeke word *Iaſme*, which ſignifieth *Violaceum*, it hath no other Greeke name, unleſſe as ſome thinke it be the *Pothos albus* of *Theophraſtus*. The firſt is called *Iaſminum* or *Gelſeminum vulgatius & album*, by all Authours. The ſecond is called *Iaſminum*, or *Gelſeminum grandius & Catalanicum*, but by *Lugdunenſis Iaſminum puniceum*. The third is mentioned onely by *Ferrarius*, in his *Flora* or *de florum cultura*. The fourth by him alſo, yet mentioned in the Catalogue of the *French* Kings Garden at *Paris*. The fifth was never mentioned by any before, and but that Maſter *Tradeſcant* is confident to call it a Iaſmine, and therefore I am content to put it with the reſt to give him content, I would be further informed of it my ſelfe, before I would certainely give my conſent.

*The Vertues.*

*Serapio* delivereth it, that the white Iaſmine is hot in the beginning of the ſecond degree, that it diſcuſſeth humours, is good againſt ſalt flegme, profitable to old cold men, and profitable for catarrhs, and the grieſes that ſpring from tough flegme: the leaves either greene or dry, doe cleanſe freckles, ſpots, and diſcolouring in the face or elſewhere, and helpeth tetters or ringwormes, and the like: it is not fit that thoſe that are of an hot conſtitution ſhould uſe this, for this breedeth the headache. The flowers are very ſweete, and therefore they ſerve to ſtrow in the houſe for an ornament and good ſent, they uſe alſo in the warme Countries to lay the flowers among their gloves

or fine linnen, to give the better sent. The oyle that is made of the flowers by insolation is good for any cold part of the body to warme it, and to ease the paines of the crampe, and stitching in the sides.

## CHAP. LI.

*Polemonium sive Trifolium fruticans vel Iasminum luteum vulgare.*
Shrub Trefoile or the ordinary yellow Iasmine.

ALthough as I said in the Chapter before, this plant is not of the Iasmines, yet because it hath by time obtained that name, and that the flowers thereof in forme resemble the white Iasmine, I thought it good to joyne it next unto them, because I would not put it into their Chapter. It spreadeth white rootes in the ground farre about, rising up in sundry places with many tall and slender twiggy branches, green at the first, but after of a darke grayish colour, whereon are set at severall distances, three small darke greene leaves together on every stalke, the end leafe being the biggest: at the joynts with the leaves come forth the flowers, each singly by it selfe upon a stalke which are long and hollow, ending in five leaves usually, yet sometimes in sixe, very like unto the flowers of the white Iasmine, but yellow, and thereupon it was called a yellow Iasmine, which being past, there follow other round blacke shining berries of the bigness of a great Pease or bigger, full of a purplish juyce which will colour ones fingers that shall bruise them.

*Polemonium sive Trifolium fruticans vel Iasminum luteum vulgare.* Shrubbe Trefoile, or the ordinary yellow Iasmine.

*The Place* and *Time.*

This groweth plentifully about *Mompelier*, and abideth well any where in our Country: it flowreth in *Iuly*, but we seldome see ripe fruite thereon.

*The Names.*

It is called *Polemonium Monspeliensium* by *Gesner*, *Lobel*, *Cameratius* and *Lugdunensis*, and *Trifolium fruticans* by *Dodonæus* and *Tabermontanus*, who also calleth it *Ruta baccifera sive trifolia*, and *Gesner Ruta capraria Gallorum Monspeliensium*, and by some *Iasminum luteum Italicum*, yet *Columna* calleth it, *Iasmini species trifolia non videtur ad Polemonium accedere*, *Besler* in *horto Eystetensi*, sheweth one with foure leaves, that are greener, and not so sharpe pointed, and *Bauhinus Iasminum luteum vulgo dictum, bacciferum*, who also giveth this note of it, that at *Mompelier* it is often found but with one leafe alone upon a stalke, although in Gardens it hath three. It is very doubtfull whether it should be the *Polemonium* of *Dioscorides* or no, for you have here the judgement of *Columna*, *non videtur ad Polemonium accedere*, although *Lobel* would make it agree in all things. Some would make it therefore a *Cytisus*, but it agreeth thereto in nothing, but in having three leaves together. We cannot learne what *Italian*, *French*, or *Dutch* name it hath, but in *English* it may be called Shrubbe Trefoile, according to the Latine, but *Gerard* saith, it is called Make bate, yet I know not where nor by whom: it is usually called now adaies the yellow Iasmine from the likenesse of the flowers.

*The Vertues.*

We know not of any knowne property it hath for certaine, and therefore to give you the particular Vertues of *Polemonium*, when as peradventure not any one can belong thereunto, were needelesse, and the ground of a great errour.

## CHAP. LII.

*Syringa.* The Pipe tree.

ALthough I have shewed you these five sorts of Pipe trees in my former Booke, yet I thinke it not unfit to present you with them againe here, and give you a full description of that sort that was defective there.

1. *Lilac Matthioli sive Syringa flore cæruleo.* The blew Pipe tree or Lilac.

The blew Pipe tree riseth sometimes to be as great as a meane apple, yet usually it groweth nothing so great, having oftentimes suckers rising from the roote, the younger branches being covered with a grayish greene barke, and the elder with a darker, having within them a pith like the Elder, with two faire broad, smooth deepe greene leaves, small pointed at the ends, set at every joynt, which are some distance one from another, many of them folding the leaves inwards, standing on long footestalkes: at the toppes of many of the branches come forth many long hollow blewish purple flowers, ending in five leaves, in a long tuft together,

1. *Lilac seu Syringa flore cæruleo.*
The blew Pipe tree or Lilac.

3. *Syringa Persica sive Lilac foliis incisis Persicum, Iasminum Persicum dictum.* The blew Persian Iasmine or Pipe tree.

4 *Syringa flore alba simplici.*
The single white Pipe tree.

5. *Syringa Arabica flore duplici.*
The double white Pipe tree.

ther, hanging downe, and are of a small sent; the flowers being past, there come sometimes, but not often in our Country, long and flat cods, consisting as it were of two sides, with a thin skin in the middle, wherein are contained two long flattish red seede: the rootes are strong and grow deepe in the ground.

2. *Lilac sive Syringa flore lacteo sive argenteo.* The silver coloured Pipē tree.

This Pipe tree differeth not from the former, either in stemme or branch, either in leafe or flowers, or manner of growing from the last, but onely in the colour of the flower, which is of a milky silver colour, which hath a shew of blew therein, comming somewhat neere unto an ashcolour.

3. *Syringa Persica sive Lilac Persicum incisis foliis Iasminum Persicum dictum.*

The blew *Persian* Iasmine or Pipe tree.

This *Persian* Iasmine (or *Persian* Lilac, whether you will) is a sharub, or shrubby plant, never rising into a tree like the former, yeelding many twigges, or stems and suckers from the roote, whose wood is soft having a pith in the middle, as the other, seldome rising above a mans height, having a smooth blackish greene barke, with sundry winged leaves thereon, on all sides, some whereof as well those below as above, will be whole without any division therein, resembling a Privet leafe, others will be cut in on the one side or the other, or both, and divers will be halfe like, or wholly like the posture, and divisions of the *Catalonian* Iasmine resembling it so neerely that thereby it came to be called a Iasmine: at the toppes of the sprigs and branches stand many tufts of flowers, in a long spike, of foure leaves a peece, so like unto the former Lilac, that at the first view of them you may truely, define it to be a Lilac, the colour onely excepted, which in this is more purplish, and of as sweete a sent or rather stronger: after the flowers are past, follow the like small long blackish seede, inclosed in somewhat long and pointed huskes like the former but lesser. This doth in every part, except the growth and leaves, come neerest to our ordinary Lilac, and doth in nothing but the leaves resemble a Iasmine: for both the wood is white and pithy and the flowers grow in tufts or spikes, and appeare in *May* when no Iasmine doth, but the Lilac: the seed likewise is contained in hard huskes, as the Lilac and not as the Iasmine, like a Lupine, of a soft substance, and lastly the taste of this is somewhat harsh, with some astriction in the end, and the Iasmine hath a bitter sharpe biting taste, and very astringent withall. Yet as I said before, this is most likely to be *Serapio* his blew Iasmine. The roote spreadeth many branches with fibres to them, under ground, and may very well be propagated by the suckers: this holdeth his greene leaves in the Winter, no more then the others doe.

This assuredly is the *Iasminum cæruleum* of *Serapio*, whereof formerly there was great doubt among Herbarists whether there were such a thing in *rerum natura*, very many denying it, because they either never saw this or never considered it.

4. *Syringa flore albo simplici.* The single white Pipe tree.

This Bush never beareth any great stem or body, but shooteth forth most usually many pliant brownish twigs or shootes, and grayish when they grow elder, being pithy in the middle like the former, at each joynt stand two leaves somewhat like the former, but more rugged or crumpled, a little pointed at the ends, and dented about the edges: the flowers grow at the toppes of the branches, many set together, consisting of foure leaves, as large as the Muske Roses, and of the same creame colour, with many small yellow threds in the middle, of a strong sweet, full and heady sent, not pleasing to a great many, by reason of the strong quickenesse of the sent: after which followeth the fruite, flat at the head, with many leafy scales compassing it, wherein is enclosed small long seed: the rootes runne not deepe into the ground, but spread with many fibres thereat.

5. *Syringa Arabica flore duplici.* The double white Pipe tree.

The double Pipē tree from a short thicke stumpe, not rising high above the ground, shooteth forth divers long and slender branches, whereon grow large leaves, somewhat like unto the last, but not so rough or hard, nor dented at all about the edges, two alwaies standing one against another at the joynts, but set or disposed on contrary sides, and not upon two onely; at the ends whereof come forth three or foure flowers, every one on a stalke by it selfe, which are long and hollow below, like the white Iasmine, and have a double row of white round pointed leaves; five or sixe in a row at the toppe, seeming like unto a double white Iasmine flower but larger, with some yellownesse in the middle, which is hollow, of a very strong and heady sweete sent like the single kinde, and abide long flowring, especially in the hotter Countries, but is very tender, and not abiding the least cold weather with us, the cold windes greatly molesting it in the hotter Countries, and must therefore be kept with us as charily as Orenge trees, or rather more.

*The Place* and *Time.*

The first groweth in *Arabia* as *Matthiolus* thinketh, who had it from *Constantinople*: but now is plentifully to be found in many Gardens of our Land as well as others. The second is a stranger with us as yet. The third is very like to come first out of *Persia*, as the name importeth, it is now to be seene with Master *Tradescant*, at South *Lambeth*. The fourth is almost as frequent as the first, but the originall place is not certainely knowne. The last hath the originall from *Arabia*, as the name importeth. The first, second, and third, doe flower in *May*, the fourth in *June*, and the last later.

*The Names.*

Some have taken these to be kindes of Iasmines, and that therefore the *Arabians Sambac*, doth as fitly agree to these as to the Iasmines, for *Cæsalpinus* taketh the first, which *Matthiolus* called *Lilac*, and so divers others after him, to be the *Iasminum cæruleum Mauritanorum*, or the *Ligustrum Orientale* (neither of which it can be, for the *Cyprus Pliny*, as I have shewed you before, may most fitly be called by that name, and the blew Iasmine is as I said very probable to be the third, which we call the *Persian* Iasmine) *Clusius*, *Camerarius* and others, call it *Syringa cærulea*, and *Lobel* and others *Syringa cærulea Lusitanica*, it is thought that *Bellonius* understandeth this plant, where he saith that the *Turkes* have a shrub with Ivy leaves alwayes greenē, bearing violet blew flowers on a long spiked stalke many together, of the bignesse and fashion of a Foxetale, and thereupon called Foxetale in their tongue, yet this of ours beareth not greene leaves in Winter, as *Bellonius* saith. *lib.* 3. *c.* 50. that doth, whether it doe therein differ from ours, or whether he be mistaken, it resteth doubtfull. Some as *Lugdunensis* saith, have taken this plant to be the *Ostrys* or *Ostrya*, of *Theophrastus*, because it beareth small seede like unto Barley, and some would have the white *Syringa* here set forth, to be his *Ostrys* likewise for the same cause, but I have shewed you the true *Ostrys Theorhrasti* before, as *Clusius* hath sufficiently declared it. The second is remembred in no Authour

but

but the *hortus Eysteteusis*. The third is called by *Prosper Alpinus*, in his Booke *de plantis exoticis Ligustrum nigrum*, by which name it came first to *Bauhinus*, as he saith, out of *Italy*, and afterwards from *Signiour Contareni* his Garden, by the name of *Syringa laciniatis folijs*, which he altereth to *Ligustrum laciniatis folijs*, but it seemeth he had but onely a branch to see, without flower, as it is in his description, and therefore could not further determine upon it, but I have often seene it both in and out of flower, and doe here give you both a full and true description of the plant, and the name that both we and *Iacobus Cornutus* set it out by, in his Booke of *Canada* plants, *viz. Agemlilag Persarum*, which as he saith signifieth *Lilac Persicum*. *Agem enim Persideni significat, & Lilac florem*, but came to us by the name of *Iasminum Persicum*, because many of the leaves are formed very like those of *Iasminum Catolonicum*, as I have shewed you in the description, yet the truest name to be imposed on it, is *Lilac Persicum*, as I have before shewed you, and this is that *Lilac laciniatis folijs*, that J gave you understanding of in my former Booke. The fourth is called *Frutex coronarius* by *Clusius*, and *Syringa alba* by all other Authours but *Lobel*, who calleth it *Syringa Italica*, not that he ever saw it growing naturally wilde in *Italy*, but that he there found it very frequent in their Gardens, *Bauhinus* calleth it *Syringa alba sive Phyladelphus Athenæi*. The last is called *Sambac Arabum sive Iasminum ex Gine*, so that it may not unfitly be referred to either, it is called *Syringa Italica flore albo pleno*, by *Besler*, who set out the great Garden of the Bishop of *Eystot*, although *Bauhinus* seeme to make two sorts of it, as his custome is in many other things, which it is likely he never saw, but upon *Alpinus* his resembling the leaves unto those of the Orenge tree, for thereby he maketh his distinction. We may call it in *English*, either the double white *Syringa* or Pipe tree, or the double white Iasmine, according as it is in Latine, which you will, although the single white hath nothing the like resemblance in the flower to a Iasmine.

*The Vertues.*

There is no use of any of these in Physicke, that I know, and are but as ornaments in a Garden, and for the beauty and sweetenesse of the flowers there cherished, unlesse any would make a perfume of the flowers, by infusing them in the Sunne with oyle of sweete Almonds, or draw a Chymicall oyle out from the said flowers, by distillation, onely the last *Alpinus* sheweth the *Egyptians* doe use more for ornament to trimme up and perfume themselves, then for to helpe them in their diseases, nevertheless, they make saith he an oyle thereof, which their women use in their bathings to mollifie the harddesse and warme the coldnesse of the mother, for by their experience they have found it to be very helpefull for hard kernels and tumours in the flesh, and to cause a more easie and speedy delivery in travaile of childbirth by drinking this oyle warme and annoynting the wombe also: Some use likewise to drinke that oyle warme, and to annoint the stomacke outwardly therewith, against the cough and shortnesse of breath, and against the dangerous pleurisie, where one can hardly bring up the flegme, or their spittle, and against Impostumations in the lungs, and against the violent paines in the stomacke, bowele, or privities: the oyle is made after the manner aforesatd, either with oyle of Almonds or *Sesamum*, and the flowers steeped and sunned.

## CHAP. LIII.

1. *Oleander flore rubro.*
The Rose bay with red flowers.

### 1. *Oleander sive Laurus Rosea.*
The Rose bay or Oleander.

THere is of this Rosebay two sorts, the one with crimson coloured flowers, the other with white, which are both so like in leafe and growing, that very hardly they can be distinguished, before they be in flower, and therefore one description shall serve for them both, and so might one figure also, but that I had them both ready cut in my hand, as I had many others, that are inserted into this Worke. The stemme or trunke hereof groweth in time with us (but much more in the hotter climates) to be as big below as a reasonable mans wrist, and divideth it selfe upwards into many stalkes, three for the most part rising at a place, and from each of them likewise, three other branches, and so by degrees from three to three, as long as it groweth, the lowest part of the branches being bare without leaves, and keeping them only at the tops al the Winter, being long & somewhat narrow, more like to those of the Peach, then Bay tree, but thicker and harder, of a darke greene above and yellowish below, the flowers come forth at the tops onely of the branches, of a deepe crimson colour while they are in the bud, and being blowne consist of foure long and narrow leaves, with round ends, somewhat twining themselves, of a paler red colour, tending to a deepe blush, and in the other are white, without any mixture of other colour therein, but the greene leaves are paler or fresher: after which come long crooked pods, hard or wooddy almost on the outside, and browne in the hot Countries, but was never seene to beare ripe pods, I thinke in our Country wherein is contained brownish flat seede, wrapped in a great deale of most fine brownish yellow downe, as fine almost as silke, the pods being somewhat like unto the pods of *Asclepias* or *Periploca*, but larger, flatter, and harder.

2. *Nerij*

1. *Oleander flore albo.*
The Rose bay with white flowers.

2. *Nerij facie arbor Indica.*
An Oleander-like Indian tree.

3. *Nerij facie arbor Indica.* An Indian Oleander-like tree.

Because *Lobel* onely hath set forth this branch comparing it to the Oleander, I thought good to joyne it next thereunto, although wee have no further knowledge thereof then his relation which is thus. Seven or nine of these together like unto sheathes of leather, a foote, or a foote and a halfe long, every one of them resembling a slender Lamprey, did hang downe from one place of the branch, which was like a pithy Marsh Elder knotty pale browne sticke, so nearely resembling the cast skin of a Snake, or the dead body it selfe, that it might very well fright children therewith, although stuffed on the inside with woolly skins, at the same knot with these skins came forth some flowers, growing out of small huskes, as the figure expresseth them unto you.

*The Place* and *Time.*

The first with red flowers groweth in *Greece, Spaine, Italy, &c.* in many places but that with white in no place but *Candy*, that we can heare of, and flower in *Iuly*, the other is an unknowne stranger.

*The Names.*

It is called in Greeke Νήριον. καὶ Ῥοδόδενδρον, καὶ Ῥοδοδάφνη, *Nerium*, and *Rhodendron*, and *Rhododaphnes*, and so also in Latine by most Authours, but *Laurus Rosea* by *Apuleius* and *Lobel*, and *Rhododaphne* by *Camerarius*. The last is so entituled and desciphered as I here set it downe.

*The Vertues.*

We have nothing to relate of the last, but of the Rose bay, *Dioscorides* saith it is death to Mules, Dogs, Asses, and many other foure footed beasts, that shall eate thereof, but that it helpeth men that are stung by Serpents, the leaves and flowers, being taken in Wine, but *Galen octo. simplicium*, seemeth contrary hereunto, saying that outwardly applyed, it hath a digesting property, but inwardly taken it is deadly, both to man and all sorts of cattle. *Matthiolus* therefore to reconcile these two sayings, finely defineth *Dioscorides*, to understand such men as are bitten or stung by Serpents, *Galen* by such as are in health and not stung: For after the same manner, *Cantharides* saith *Avicen*, doth helpe those that are bitten by a mad dogge, and *Euphorbium* by the Scorpion, and so likewise divers other dangerous or deadly medicines, resist the venome of other things: But *Cordus* would interpret it another way, that is, that taken inwardly it was poyson, but outwardly applyed it did resist it, and saith moreover that the flowers are deadly, but in some places and at some times. Yet *Dioscorides* words are plaine, inwardly taken and drunke in Wine, with some Rue, and so *Pliny* also relateth it, as taken from *Dioscorides*. *Galen* saith that the chiefe Champions in Wrastling and Running had their backes paid with Rose bayes. The Honey of *Pontus* also was accounted deadly, because the Bees there fed on the flowers hereof, as well as on those of *Acomite*. *Lucius Apuleius* in his Asses forme, and *Lucian* also, as they write of themselves, had like to have caught their banes by mistaking the flowers, hereof for Roses, which should have holpen them.

## CHAP. LIV.

### *Cytisus.* Tree Trefoile.

HAving in the last Chapter shewed you a Trefoile Iasmine, which some as I said, take to be a *Cytisus*. I thinke it not amisse to set downe the kindes of *Cytisus*, next unto it, and because there is such diversity among them, I would distinguish them into two sorts, that is, into the right *Cytisus*, and those that come neerest unto it: and into a bastard kinde, that is some that are very unlike in many things, although like in some, and others like in many yet unlike in some: the sweetnesse in their taste and whitenesse in their leaves and stalkes, declaring their nighnesse unto the true sort: their blacknesse and bitternesse, to the bastard kindes: of the first we will speake in this Chapter, and of the other in the next.

1. *Cytisus Galeni creditus, Maranthæ Cornutus.* The supposed true *Cytisus* or horned tree Trefoile.

This *Cytisus* (as *Galen* saith groweth to the height of the Myrtle, or as *Pliny*, *Columella*, and *Straboto*, to the heighth of a meane tree) which many tooke as *Lugdunensis* saith, for no other then the *Medica Lunata*, and is yet described by *Besler*, as it grew in the Bishop of *Eystot* his Garden (to be in some sort answerable to what *Matthiolus* setteth forth of it, for acknowledging his former errour, in mistaking the *Trifolium caballinum* to be *Cytisus*, and finding in *Galen Cytisus* was a shrub and not an herbe, he sheweth this plant, which he received from *Cortusus* as the right, and therefore could be no *Medica*, which is a small creeping herbe, as all the sorts are) and groweth to be two cubits high, covered with a grayish or ash-coloured barke, the wood whereof is firme and hard: the leaves are hoary white, as is the whole shrub, and grow without order three together on long footestalkes: the flowers are of a gold yellow shining colour like unto Broome: the seede groweth in broad crooked cods.

2. *Cytisus Creticus incanus sive Ebenus Cretica Belli.* *Candy* tree Trefoile, or *Candy* Ebony.

This *Candy* plant riseth up to above a mans height, that is, foure or five cubits growing writhed or crooked, and of the thicknesse of ones arme, covered with an ash-coloured barke, the leaves are gray or white, longer and narrower then the former, and grow not alwayes three, but sometimes foure or five, upon a long footestalke, the flowers grow at the ends of the branches, in a tuft together like unto those of the Medow Trefoile, or common three leaved grasse, of a gold red colour, and greater then they: in the middle of each flower stand many silver white shining threds, as fine as haires, set in grayish huskes, wherein the seed is enclosed afterwards, which is like unto that Trefoile likewise: the wood is very firme and massie, and of the colour of blacke Ebony, from whence *Honorius Belli*, did call it so.

3. *Cytisus incanus Germanicus.* The *Germane* hoary tree Trefoile.

This *Germane Cytisus* shooteth from the roote sundry slender hoary stalkes, with three somewhat long leaves, at sundry places of them somewhat hoary also on the backeside, more then on the upper part, the middle rib being somewhat great, of a kind of sweetish taste, and a little sweete in sent also: the flowers are yellow like the other sorts or Broome flowers, standing many together one above another at the end of the branches, after which follow hairy, and somewhat hoary, little long, narrow and flat cods, containing therein small seed like broome, tasting like a Vetch: the roote is wooddy, dispersing it selfe under ground divers wayes.

1. *Cytisus Galeni creditus Maranthæ Cornutus.*
The supposed true Cytisus or tree Trefoile.

4. *Cytisus Hispanicus arboreus.*
The *Spanish* tree *Cytisus*, or tree Trefoile.

This Cytisus riseth up with one stemme usually, covered with a darke grayish barke to the height of a man, saith *Clusius* in *Spaine*, but higher with us, spreading sundry short branches all about, whereon are small pale greenish Trefoile leaves, on the upper side, and set with a little reddish hairynesse underneath, the yellow flowers are somewhat longer then others, and come forth at the foote of the leaves, in sundry places, usually two or three at a place, which turne into small short and flat cods, lesser then Broome cods, and somewhat blackish when they are ripe containing small flat and blackish seed within them: as small as Broome seed, as we have observed them, although *Clusius* saith hee saw none.

5. *Cytisus incanus major folijs pinnatis sive quinti species altera Clusij.*
The great hairy tree Trefoile.

This groweth greater and more upright then the third by much, whose branches also are thicker and more hairy: the leaves are twise as big, the flowers of a deeper gold yellow colour and the cods larger.

6. *Cytisus Hispanicus incanus sive sextus Clusij.*
The low *Spanish* hoary *Cytisus*.

The shootes of this Cytisus are not above halfe a yard long, slender and hoary, whose Trefoile leaves on them have the two lowest smaller then the middlemost, which is twise as long, but of an hoary ash-colour, standing on short footestalkes, of an astringent drying taste, the flowers stand with

the

2. *Cytisus Creticus incanus sive Ebenus Cretica Belli.*
Candy tree Trefoile or Candy Ebony.

3. *Cytisus incanus Germanicus.*
The Germane hoary tree Trefoile.

4. *Cytisus Hispanicus arboreus.*
The Spanish tree Cytisus or tree Trefoile.

6. *Cytisus Hispanicus sextus Clusij.*
The low Spanish hoary Cistus.

7. *Cytisus Austriacus sive septimus Clusij.* The Austrian or Hungarian low Cytisus.

10. *Cytisus octavus Gerardi.* *Gerard* his eighth Cytisus.

the leaves at the joynts all along the branches, two or three together sustained by soft hoary white huskes, wherein they stand, why *Gerard* should call this kinde *semper virens*, and his Corrector after him so to let it passe, I know not, for neither *Clusius* first set it forth, nor any since him that have written of it, have so related it.

7. *Cytisus Austriacus sive septimus Clusij.* The *Austrian* or *Hungarian* low Cytisus.

The slender lithy twigges of this Cytisus are pliable and hard to be broken, lying on or neare the ground, which are bare of leaves, unto the branches whereon they stand without order upon long footestalkes, shorter and greener then those of the third or *Germane* sort, and more hairy, greenish above and gray underneath: the flowers grow two or three at a joynt as the last and at the ends of the branches also, yellow at the first, but before they are quite past, turne more gold yellow, so deepe that they seeme red withall: the cods are small flat and hairy, with small browne seede within them.

8. *Cytisus Pannonicus sive septimi species altera Clusij.* The hoary low Cistus.

This is somewhat like the last in the slender pliable twigs, leaning downe to the ground and leaves like them: the flowers also are like unto them, but stand foure or five together, at the ends of the branches, and not at the joynts as in the last: the cods and seede differ not there-from, but the leaves are a little hoary, and so are the cods also.

9. *Cytisus albicans Alpinus.* The whitish mountaine Cytisus.

There is little difference in this, as by the notes thereof appeareth from others in the branches or leaves, but that at some places two or three trefoile leaves, are set at a joynt, and the flowers are paler.

10. *Cytisus octavus Gerardi.* *Gerard* his eighth Cytisus.

*Gerard* and his Corrector after him, mention this Cytisus as taken from *Lobel* and *Pena*, when as it agreeth with neither of those that are extant in their *Adversaria*, neither doth *Bauhinus* quote him for it, as he doth all others that he knew; for the eighth of *Tabermontanus*, which might seeme to be this, *Bauhinus* noteth to be his *hirsutus*: the chiefest difference therein as *Gerard* saith, is in the leaves, which are a little dented on the edges, which yet are not seene in the figure.

*The Place* and *Time.*

The first of these *Bartholmeus Maranta* found in *Naples*, and *Honorius Bellus* in *Candy*, as he did the second also: all the rest, except the sixth and last were found by *Clusius* in *Hungary*, *Austria*, and the parts thereabout: they all flower in the Spring of the yeare, but some earlier and some later, and give their seede in *August* and *September*.

*The Names.*

It is called in Greeke κύτισος, and *Cytisus* in Latine, a *Cythnio insula*, as *Pliny* saith, from whence it was carryed to the *Cyclades*, to the Greekes, and after to the Latines, for the wonderfull fruitfullnesse it procureth both in men and cattle, but especially in their heards and flockes: the former times as *Matthiolus* and *Tragus* shew by their

mistakings of the true *Cytisus*, were smally verst in the knowledge of plants, in that for the most part, whatsoever herbe offered it selfe next to hand, that had but some shew like the true, it was presently accepted for true, although after upon better examination it proved farre short thereof. The first of these is the *Cytisus Marantha* of *Matthiolus*, *Lobel*, *Lugdunensis*, and all others, and taken by *Camerarius* and others, to be the *Cytisus verus* of *Galen*, *Dioscorides*, *&c.* the *Italian Pona*, confounded this and the next together, as *Bellus* seemed to doe also, in calling it *Cytisus Creticus*, which he said is like unto that of *Marantha*, yea it is the same as he thought, having the like crooked cods, to be the *Ebenus Cretica*, but he afterwards corrected himselfe, in that it differeth much in the heads of flowers and seede, from that of *Marantha*, but *Bauhinus* saith, he received from *Bellus* branches of each of these to shew the difference, so that this first is the *Lignum Rhodium*, or *Cytisus verus*. And the second is that which he first called *Cytisus Creticus*, and by the *Cretanes Archontoxylum*, that is, *nobile lignum*, which for distinctions sake he calleth *Ebenus Cretica*. The third is the first *Cytisus* of *Clusius* in his history, and the *Cytisus prior* of *Lobel*, and likewise the *Cytisus albus sylvestris* of *Cordus* in his History, although *Bauhinus* doth sever them into three sorts, as who so will heedefully marke them, shall soone see that there is no such difference in them, to cause them so to be severed. The fourth is the third *Cytisus* of *Clusius*, which *Lobel* and *Lugdunensis* call *quartus Hispanicus*, because it is so in his *Spanish* Observations, but we take them all in this worke, according to the numbers expressed in his History of plants, as I have shewed you in diverse places before. The foure last sorts have in their titles, the number that you shall finde them in *Clusius*.

*The Vertues.*

The leaves of all these sorts (for it is probable they doe not one differ from another) are cooling, and doe disperse tumours, and hard swellings, if they shall be beaten with bread and so applyed, the decoction of them being drunke, provoketh urine, for as *Galen* saith, the leaves have a digesting quality, with some temperate humidity in them also, as Mallow leaves have, *Columella* sheweth that in former ages, there was much profit made by the feeding of sheepe herewith to give store of milke, and not onely to fatten them, but Bullockes and Goates also, and Hens, and all other sorts of cattell: but was planted also for Bees to feede on, as from whence they did gather more honey, then from any other plant whatsoever, and besides it abideth greene eight moneths of the yeare for their pasture, and may be kept dry the rest of the yeare following, as the dry fodder: if women that be Nurses have not any store of milke in their brests, let them steepe some of the leaves and young branches hereof in faire water all night, and being strained forth in the morning, let them take three parts thereof, with a fourth of wine, which will breede good store of milke in them, and make their children strong and able: the dryed leaves steeped all night in water, and boyled afterwards, strained and drunke is as effectuall as the juyce.

## CHAP. LV.

*Pseudocytisus.* The bastard or base tree Trefoile.

THere are divers sorts also of this base or bastard kinde to shew you, whereof one is the most adulterate of them all, which therefore shall be last exprest.

1. *Pseudocytisus Hispanicus primus.* The first *Spanish* base tree Trefoile.

This first base tree Trefoile groweth up to the height of a small tree, whose body and branches are covered with a grayish barke, the younger twigges being hoary white, the leaves are many, and smaller then in any other sort of Cytisus, three alwayes set on a stalke, of a pale greene colour, and abiding in the Winter, contrary to any of the rest, of a bitterish taste, the flowers are yellower and smaller then Broome flowers, standing as it were spike fashion at the end of the branches, after which come rough hairy long pods, wherein is thicke flattish blacke seede, smaller then that of Broome: the roote is wooddy and spreadeth divers wayes, the wood is firme and yellowish.

2. *Pseudocytisus Hispanicus secundus.* The second *Spanish* base tree Trefoile.

This second *Spanish* sort, riseth not much above a yard high, full of shootes from the rootes, which are branched forth and wholly white, having hoary Trefoile leaves, never open but as it were folded together, the middle rib being great, of an extreame bitter taste: the deepe yellow flowers, are somewhat sweete and stand at the end of the branches like the former and the pods that follow are long and rough, of a blackish purple colour, the points being turned downewards, with greater and blacker seede in them: the roote is like the former.

3. *Pseudocytisus niger.* Blacke base tree Trefoile.

This base tree Trefoile groweth with the limber pliant shootes, it bringeth forth not so high, but straighter and greater then the last, the barke of them being of a darke grayish colour, beset with small Trefoile leaves, somewhat round, and a little bitter in taste, and of a darke greenish colour, the flowers grow at the toppes of the stalkes many together spike fashion, of a yellow colour and pretty sweete sent, like unto honey, the cods that follow are somewhat long and flat, with brownish seede in them.

4. *Pseudocytisus foliis subrotundis.* Base tree Trefoile with roundish leaves.

The stem hereof hath sundry branches growing forth from it, and set with small roundish darke greene leaves, upon very short footestalkes: the flowers, are smaller then those of Broome, and yellow, but more store set together at the ends of the branches, then the smallnesse of the plant might seeme to beare, of a pretty sweete sent, and a pulselike taste, the pods and seede are small like the last.

5. *Pseudocytisus Hispanicus Bauhini.* *Bauhinus* his *Spanish* base tree Trefoile.

This *Spanish* base tree Trefoile hath hard round striped stalkes, foure or five foote high, branched into sundry branches, somewhat woolly, stored with divers small Trefoile leaves, of a pale greene colour, the flowers are small and yellow like the others, unto which succeede many small pods like unto those of Birds-foote, three, foure, or five joyned together on a stalke, with small flat blackish seede in them: this is not the same with the first of these base tree Trefoiles here set downe being much different.

6. *Cytisus facie quibusdam Alissum fruticans.* A Cytisus-like unlike plant.

Because others before me have placed this plant as last of the Cytisus, so must I for this time, which else might in

1. *Pseudocytisus Hispanicus primus.*
The first Spanish base tree Trefoile.

2. *Pseudocytisus Hispanicus secundus.*
The second Spanish base tree Trefoile.

3. *Pseudocytisus niger.*
Blacke base tree Trefoile.

4. *Pseudocytisus foliis subrotundis.*
Base tree Trefoile with roundish leaves.

in some sort have beene set with the other *Alyssa*, the description whereof is thus. From a tough wooddy roote grow up sundry pliant hoary greene stalkes, spreading into branches, set with divers hoary greene leaves together, contrary to all the other *Cytisi's*, yet each leafe by it selfe, somewhat like unto them, but thicker and hairy also, the flowers are many and yellow, that stand at the toppes, spike fashion, composed of foure leaves like to Stocke Gilloflowers, after which come seedes in round pods.

*The Place* and *Time.*

Three of these grow in *Spaine*, the former two found by *Clusius*, and the last by some other, the other two in *France* and *Germany*, and flower and seede in the time of the former.

*The Names.*

The first of these is the first *Cytisus* of *Clusius*, which *Lobel* and *Lugdunensis* call *Cytisus Hispanicus primus*, by *Dodonæus Pseudocytisus prior*, and *Bauhinus Cytisus minoribus foliis ramulis tenellis villosis*. The second is *Clusius* his second *Cytisus*, called also *Cytisus secundus Hispanicus* by *Lobel* and *Lugdunensis*, and by *Dodonæus Pseudocytisus alter*. The third is the *Pseudocytisus seu niger Cordi*, the *Cytisus niger sive major* of *Camerarius*. The fourth *Cytisus* of *Clusius*, the *Cytisus minor* of *Gesner*, which *Lugdunensis* calleth *Cytisus Gesneri*, and by *Bauhinus Cytisus glaber nigricans*. The fourth is the *Cytisus alter minor* of *Lobel*, which *Eystetensis* calleth *Trifolium arborescens*. The last *Bauhinus* onely hath described in his *Prodromus*, by the same title I doe here give it you.

*The Vertues.*

We have nothing recorded of any particular, any of these base shrubbes are indued withall, and although some may thinke, that they are of the same quality with the former, I am not of that opinion, in regard they are all much more bitter then the former, and some intensively bitter, which can be no helpe to encrease milke, in any creature, nor yet to fatten them as the former doe.

*6. Cytisus facie quibusdam Alissum fruticans.*
A Cytisus-like unlike plant.

## CHAP. LVI.

### *Cupressus.* The Cypresse tree.

Some doe make two sorts of Cipresse trees, the male and the female, the one that spreadeth more then the other, which groweth more upright, not much differing in any thing else, which maketh me thinke the diversity riseth from the soyle or some casualty, and that the male which spreadeth is not a distinct *species*, which preserveth the kinde naturally as all other things doe, especially seeing as *Theophrastus* saith, the one doth degenerate into the other, and that both doe beare nuts and seede alike. I shall therefore under one make mention of both sorts, if they be so, and shew you that the Cypresse groweth to be a great tall upright tree, spreading out the branches so even round about, that it seemeth to be so formed by Art, being small below, not farre above the ground, then spreading out larger, yet keeping a round close compasse and afterwards spiring up to the toppe, lesse and lesse, very well representing a *Piramis* or Spire steeple, the body and armes are covered with a reddish barke, the leaves are ever green, but loosing much of the verdure in Winter, which it regaineth the next Spring after, and somewhat long, slender, and flattish round, parted very much and somewhat resembling Savine, of a resinous sent and strong taste: some trees are seene in some places to be more spreading in their branches, and not abiding so close, especially when they grow old, and doe beare their small yellow flowers, and their fruite, or nuts, as they are called afterwards, which grow here and there among the boughs, cloven or opening into divers parts growing ripe, but close and hard while they are young, of a russet browne colour, wherein are contained small brownish seede, but not so small as motes in the Sunne, as *Matthiolus* and others make them to be: the roote spreadeth much, but not very deepe: the wood is reddish, very firme and durable, not subject to corruption or wormes, but defending all other things, by the strong heady sent it hath, from all mothes and wormes, it yeeldeth out of the body of the tree, a kinde of liquid Rossen, like unto that of the *Larche* and Turpentine trees, of a very quicke and sharpe taste.

2. *Cupressus Americana.* The Cipresse tree of *America.*

Although I doe not take this to be a true Cipresse tree, yet because it hath obtained that name by all our travellers into the hether or Northerne parts of *America*, where it is found in sundry Countries thereof, let me joyne it here untill by a better regard I may place it in a fitter. It groweth in some places to be a very goodly tall tree, fifty, sixty, yea eighty foote high, without any branch, and neere three fathome compasse at the lower end, and then spreadeth sundry large armes and branches, beset with many winged leaves, which are very fine, small, smooth, plaine, and not square, crumpled or plaited as the true Cipresse is, and somewhat longer also, set on both sides of the stalkes, without any certaine order, being not alwaies opposite: the nuts are somewhat like those of the Cipresse but greater, with thicker, more open scales and greater seede within them. The wood smelleth somewhat

what sweete, which in part caused it to be termed a Cipresse. Whether this should be that *Thuja*, of *Theophrastus*, *lib.* 8. *c.* 15. that is both in stocke, branches, leaves, and fruite, like unto the wild Cipresse, it were somewhat worthy to be scanned, whose fruite it is likely, is that *Habhel*, that *Paludanus* brought home with him in his returne from his travailes, and said it was so called in the East Countries, the figure, wherof I here give you with this branch: the nut it selfe doth much resemble the nut of this, both for forme and large thickenesse of the scales. This looseth his leaves in Winter.

*The Place and Time.*

The ordinary Cypresse tree, groweth in sundry of the warme Countries, of the Levant, Eastwards, and in many of the Isles likewise in the *Mediterranean* Sea, as *Rhodes*, and *Candy*, where it is so familiar to the soile, that it springeth up every where, of it owne accord, in the Mountaines *Ida*, and *Leuce*, if the ground be stirred a little, and that nothing else be sowne thereon, and beareth ripe fruite from *September*, almost all the Winter. The other is as is said, in sundry Countries of the North *America*, whose seede was brought by Master *Tradescant* from *Virginia*, and sown here, doe spring very bravely.

*The Names.*

It is called in Greeke κυπάριττος and κυπαρισσοῦς ἀπὸ τοῦ κύειν παρισοῦντας τὰς ἀκρεμόνας, *id est, a partu parilium ramorum*, in Latine *Cypressus*, and *Cupressus* also. The *Arabians* call it *Suro*, and *Seru*, the *Italians Cypresso*, the *Spaniards El Cypres*, the *French*, *Dutch*, and *English*, *Cypres*, and the *Germanes Cypressen*.

*The Vertues.*

The Cypresse cooleth, bindeth, and dryeth without either heate or biting sharpenesse, but so much as may put the acerbity in action, yet it doth resolve and consume humidities, in putride ulcers, the pouther of the leaves with a little Myrrhe and wine, helpeth those fluxes that fall on the bladder, and provoketh urine being stopped, and without Myrrhe the fluxes also of the belly or stomacke, bleedings, and spittings of blood: the decoction of them, performeth the same likewise, it helpeth also the cough, and shortnesse of breath, by taking fasting a small draught, and if the like draught be taken every morning for many daies together, it will helpe the rupture, so as some of the fresh leaves be applyed also to the place, and well bound on; which things the nuts do performe more effectually, and in all fluxes of blood and humours: the small chips or rasping of the wood, taken in Wine provoketh womens courses, and helpeth the biting of the Scorpion, as also procureth a good colour to the whole body: the leaves bruised and laid unto fresh wounds that bleede much, doth stanch the bleeding, and so consolidateth the wound; being used by themselves, or with fine Barley meale, it helpeth Saint *Anthonies* fire, creeping ulcers, and carbuncles and the sores and ulcers of the privy parts in man or woman, and helpeth the inflammations of the eyes, and applyed with a cerote to the stomacke doth much comfort and strengthen it against castings, and other the passions thereof upon defluxions of sharpe

1. *Cupressus major sive sativus.* The Cypresse tree.

2. *Cupressus Americana, an Thuja Theophrasti Cupresso similis, cujus fructus Habhel huic assimilatur.* The American, or Virginia Cypresse with the fruite Habhel of *Clusius* which is like unto this.

humours

humours thereon, the leaves beaten with some dry figges, doe mollifie the hardnesse of tumours, and of the testicles, and consumeth the *Polypus* of the nose, which is an excressence or peece of flesh growing therein: the same also boyled in vinegar and made up with the meale of Lupines, causeth rugged nailes to fall away, and helpeth the tooth ache, the mouth being often washed therewith: the same also taketh away the Morphew, freckles, spots, and the like in the skinne, the nuts boyled in Wine, and the haire washed therewith, causeth them to grow black, and if the ashes of them be mixed with the pouther of a Mules hoofe, and oyle of Myrtles, it will stay the falling of them: the branches and nuts of the Cypresse being burned, driveth away gnats, and other such like troublesome flyes: the leaves being laid among seedes of any sort, will keepe them from being eaten with wormes, and the wood in Wardrobes will preserve garments from Mothes: the wood it selfe is in no age subject to the worme, neither will the sent decay in many yeares, and therefore much desired in chests and boxes, *Thevet* reporteth that he saw at *Damiate* in *Egypt*, a Cypresse chest that was digged ten foote deepe out of a moorish ground, and found uncorrupt in any part, which as was likely had lyen there since *Sultan Selim* subdued *Egypt* in the yeare 1512.

## CHAP. LVII.

### *Arbor Vitæ.* The tree of life.

THis tree being in some sort like unto the Cypresse, I thought good to joyne next thereunto. It riseth to be a reasonable great and tall tree, standing long in a place, covered with a darke reddish barke on the body, but more red on the branches, spreading many branches, and many small twigges bending downewards, which and the long leaves, that come from them, on both sides are flat, and plaited or braided, as it were like a braided lace, of a darke yellowish greene colour, soft and not hard or pricking, abiding greene, alwayes smelling without falling away, and tasting somewhat strong and resinous, not pleasing to many, but ready to provoke casting, yet very cordiall, and pectorall also to them that can endure it, at the ends of the branches come forth small mossie yellowish flowers, which turne into small scaly yellowish heads, wherein lie small and long brownish seede: the wood is firme and hard, and of a brownish colour.

*Arbor Vitæ.* The tree of life.

*The Place* and *Time.*

It first was brought from *Canada* by the *French*, in King *Francis* the first his time, and presented to him, and from the encrease thereof, is spread sufficiently through all the Countries neere it, and flowreth in *Aprill*, and *May*, and the fruite is ripe in *August* and *September*.

*The Names.*

This being a new found tree, hath no true, auncient Greeke or Latine name to call it by, for although most that have written of it, referre it to the *Thuja* of *Theophrastus*, *lib.* 5. *c.* 5. which he compareth both in branches leaves and fruite, unto the Cipresse tree, yet *Omne simile non est idem*; and although it hath some likenesse in the leaves, yet so it is not in the fruite, and I verily beleeve, that it is *proprium sui genus*, not to be parallelled, or made the same with any other we have, as most of the trees and herbes of *America*, are not equall to those that grow in *Europe*, the hether part of *Africa* and of *Asia* the lesse, as experience sheweth. *Lugdunensis* maketh it to be his *Thuyæ tertium genus*. Some would make it a kinde of *Cedrus Lycia*, but that beareth red berries, which this doth not. Some also have called it *Arbor Paradisea*: but it was presented to the *French* King by the name of *Arbor Vitæ*, but upon what reason or ground I know not, but ever since it hath continued that name of the tree of life. *Clusius* and *Bauhinus* say, that some would referre it to the *Bruta arbor Pliny*, but that as he saith hath whitish branches, and sweete being burned.

*The Vertues.*

Although we have no forraigne experience to report unto you, yet upon tryall of the leaves by some in our owne Land, we have found that they that were long time troubled with a purulentous cough, and shortnesse of breath, have beene much releived and holpen thereof, by the use of the leaves taken fasting with some bread and butter, as the most familiar way for some few dayes together, thereby expectorating the flegme stuffing the lungs, and so cleering the passages, as they found much good by it, and doubtlesse the resinous smell and taste, abiding dryed as well as fresh, doth evidently declare the tenuity of parts therein, and a digesting and clensing quality, which if any would put into action they should soone see the effect.

## CHAP. LVIII.

*Tamariscus.* The Tamariske tree.

I Have three or foure sorts of Tamariske, to bring to your consideration, one whereof was never published or made knowne to the world, before I gave you a hint thereof in my former Booke, which I meane to ranke with the rest here.

1. *Tamariscus folio latiore,* The *Germane* or broader leafed Tamariske.

The broader leafed Tamariske groweth but low in sundry places, over that it doth in other, for I have observed it growne in some places where it hath stood very many yeares to be a reasonable great tree, whose barke was somewhat thicke and rugged, of a darke reddish colour, the younger shootes being reddish at the first, greene after, and blackish when they are dry, beset all about with fine long darke greene leaves, as it were crisped, because they are so small and short, that stand about the longer, yet are they greater and broader then the *French* kinde: at the end of the young shootes come forth a long spike of flowers and leaves among them, each flower being made of five purplish leaves like threds, divers of them standing in a greene huske together, in which huskes when the flowers are past, grow seede lying among them, which together are carryed away with the winde: the leaves fall away every Autumne, and spring anew in the Spring.

*Myrica sive Tamariscus specierum.*
Tamariske of three sorts.

2. *Tamariscus foliis albidis.*
White Tamariske.

Of this kinde I have seene another sort very beautifull and rare, brought me by Master *William Ward*, the Kings chiefe servant in his Granary, from his house at *Boram* in *Essex*, whose branches were all red, while they were young, and all the leaves white, abiding so all the Summer, without changing into any shew of greene like the other, and so abideth constantly yeare after yeare, yet shedding the leaves in Winter like the other.

3. *Tamariscus folio tenuiore.*
The *French* or finer leafed Tamariske.

This finer leafed Tamariske doth in many places grow but into a small shrubbe also, but in others into a great thicke and tall tree, with many spreading armes and branches, whose leaves are set in the same manner, and grow after the same fashion, but finer and smaller like unto Heath, of a grayish greene colour: the flowers are smaller, and grow spike fashion like the other, being purplish at the first, but white when they are blowne open, consisting of five leaves apeece, which turne into downe with the small seede in them, and falleth away as the Willow and Poplar doe, but *Lobel* saith, they turne not into downe, but the fruite is round like Ollive stones, which as he saith being laid in the Sunne have stirred to and fro for three dayes together, having a worme within them, which was the chiefe cause of the motion, and having made a hole in the graine commeth forth: which of these is truest, seeing both affirme the matter as eye-witnesses of the relation, I know not, never having seene the tree beare out his fruite or seede with us.

4. *Tamariscus Ægyptia galla ferens.* The *Egiptian* Tamariske.

This tree groweth in *Egipt*, and other places of *Syria*, *Arabia*, and *Turkie*, as *Bellonius* saith, who observed it to be a wondrous great and high tree, growing as well in dry ground as in moist, whole woods of them growing together in each soile, whose kind is of this last described, but besides, it beareth small hard excressences, like unto great Gaules, of divers formes, some longer, some shorter, some broad, others thicke or slender.

*The Place* and *Time.*

The first groweth naturally in *Germany*, in divers places, and as *Cordus* saith, he observed two sorts, one growing neere the River of *Rhine* with a finer leafe, and firmer wood, and a little pith, and another about the *Danubius* or *Danow*, with broader leaves, and not so firme wood: The second is declared in the description: The third groweth not onely in *Narbone*, and about *Mompelier*, but in *Spaine* in divers places, as *Clusius* setteth it downe: the last in *Arabia*, *Egypt*, and the places neere thereabouts, they flower about the end of *May*, or in *Iune*, and the seed is ripe and blowne away in the biginning of *September*.

*The Names.*

It is called in Greeke μυρίκη in Latine also *Myrica*, and *Tamarix*, but of divers *Tamariscus*, and by *Pliny Bria Sylvestris* in *Achaia* as *Lugdunensis* saith. The first is called *Tamariscus*, and *Tamarix humilis* by *Cordus* and others, and

and *Tamariscus Germanica* by *Lobel*, all others call it *Myrica* or *Tamoriz sylvestris* or *altera*. The second hath no other name, but what I have given it. The third is called *Tamariscus* or *Tamarix Narbonensis* by *Lobel*, *Lugdunensis*, and others, and *Myrica*, and *Tamariscus sylvestris* by *Clusius* and *Alpinus*, and *Tamarix Gallica aut Hispanica* by *Clusius* also: The last is taken to be the *Myrica*; and *Tamarix sativa* of *Dioscorides*, by *Clusius*, *Cordus* and others, by *Bellonius Tamarix gallis anusta*. The *Arabians* call it *Chermasel*, and the former sort *Tarfa* or *Carfa*, the *Italians Tamarigio*, the *Spaniards Taray*, and *Tamargueira*, the *French Tamaris*, the *Germanes Tamarischen baum oderholtz*, the *Dutch Tamarschen*, and we in *English* the Tamariske tree.

*The Vertues.*

Tamariske as *Galen* saith, is of a elensing and cutting quality, without any manifest drying, yet it hath a little therein, but the fruite and barke are much more drying, and is very powerfull against the hardnesse of the spleene, if the roote or leaves or young branches be boyled in Wine or vinegar, and drunke and applyed outwardly to the place also, the leaves boyled in Wine and drunk, is good to stay the bleeding of the hemorrhodiall veines, the spitting of blood, and womens too abounding courses, and helpeth the jaundise, and the chollick, and the bitings of the Spider *Phalangium*, the Viper and all other venemous Serpents, except the Aspe. The barke is as effectuall, or rather more to all the purposes aforesaid, and both it and the leaves boyled in Wine, and the mouth and teeth often washed therewith, helpeth the tooth ache, being dropped into the eares easeth the paines, and is good for the rednes & watering of the eyes: the said decoction with some honey put thereto is good to stay gangrenes, and fretting ulcers, the said decoction is also good to wash those that are subject to lice and nits. The wood is held so powerfull to waste and consume the hardnesse of the spleene, that (although it is likely to be fabulous that is said thereof) fi Swine drinke, or eate their wash out of the toughes made thereof, it will waste their spleene so much, as that they will be found quite without after a while, but it sheweth that is very effectuall to consume the spleene, and therefore to drinke out of cannes or cups made thereof, is very good for spleneticke persons. The ashes of the wood are used for all the aforesaid effects, and besides doth quickely helpe the blisters raised by burnings or scaldings of fire or water. *Alpinus* saith and *Vestingius* affirmeth it, that the *Egyptians* doe with as good successe use the wood hereof to cure the *French* disease, as others doe with *Lignum Vitæ*, or *Guajacum*, and give it also to such as are possest with lepry, scabbe, pushes, ulcers, or the like and is availeable also to helpe the dropsie, arising from the hardnesse and obstruction of the spleene as also Melancholly, and the blacke jaundise that ariseth thereof.

## CHAP. LIX.

### *Erica.* Heathe.

THere are a great many sorts of Heathes, and therefore to avoid confusion I must devide them into foure Ranckes or Orders the first of those whose leaves are like Tamariske, the second like unto the Heathe-low Pine or *Coris*: the third is of those that lye or leane downe to the ground, and the last of those that beare berries.

1. *Erica vulgaris.* Common Heath.

2. *Erica vulgaris hirsutior.* Common rough Heath.

1. *Erica*

1. *Erica vulgaris.* Common Heathe.

The Heath that groweth most frequent in our Land, is a low shrubby plant, little above halfe a yard or two foote high, with rough wooddy brownish stalkes and sundry branches, plentifully stored with small short greene leaves like to those of Tamariske, foure usually set together, from the middle to the ends of the branches, stand small bottle like bright purplish flowers at severall distances about the stalkes, and ending in foure corners, in which grow small seede when they are past: the roote spreadeth deepe, sometimes this is found with white flowers, but very seldome. *Flore albo*

2. *Erica vulgaris hirsutior.* Common rough Heath.

This other Heath groweth like the former in all things, but somewhat higher, the leaves whereof are alike also, but more rough, and of a hoary greene almost white: the flowers also are like, but somewhat paler, and herein consisteth the chiefest difference: the rootes of both grow downe, and are strongly fastned in the earth: the seed is like, and so is the roote.

3. *Erica Græca Phana dicta.* The Greekish common Heath.

*Bellonius* in his first Booke of Observations, and the 53. Chapter, that giveth us the knowledge of this Heath, saith, that meeting certaine boyes that had gathered bundles of Heath about *Syderocapsa* in *Macedonia* to burne, which they called *Phana*, was desirous to know the difference betweene it and common Heath, and by them he learned this, as one especiall note of difference, that it is easily pulled up by the rootes, without any instrument to digge the ground, when as the other common sort cannot be gotten out without a spade to digge it.

*The Place* and *Time.*

The first groweth throughout the Land in waste grounds that are called Heathes, because this kinde of plant groweth most plentifully thereon: the second groweth on *Windsor* Heath, where *Clusius* saith he found it, and the last in many places of *Greece*, the first and second are found sometimes twise flowring in the yeare usually, in *Iuly* and *August*, and sometimes in the Spring also.

*The Names.*

The generall name for Heathe in Greeke is ἔρεικη, but *Tetralix* by the *Athenians* as *Pliny* saith, in Latine *Erica*, and of some *Myrica*, mistaking it, yet by *Varro Sisara*, but that particular sort here shewed you in the third place is called *Phana* now adayes by the Greekes. *Marcellus* was in a very great errour, that made Heath a kinde of Broome, because it serveth to the same use, that is, to sweepe houses. The first is by all called *Erica vulgaris*, and *Erica Myricæ folio* by *Lobel* and *Clusius* who also so calleth the second, which *Bauhinus* saith, some tooke to be the *Selago Pliniy*. The last is sufficiently expressed in the description, and here before. The *Italians* call it *Erico*, the *Spaniards Queiro*, the *French Bruiere*, the *Germanes* and the *Dutch Heyden*, and we Heath.

## CHAP. LX.

1. *Erica Coris folio maxima alba.*
The great white flowred Heathe.

THis Heath groweth the greatest of any, even as tall as a man, and yet sometimes much lower, with wooddy browne stalkes and branches, the leaves being small, round and short, somewhat like those of *Coris*, set in a *quadripartite* forme, or crosse fashion, the flowers likewise grow foure together at a space, from the middle of the branches upwards, forming a very long spike of a foote long, and are like small long and hollow white bottles somewhat sweete, the seede and rootes are like the former kindes.

2. *Erica Coris folia maxima purpurascens.*
The great purple flowred Heath.

This differeth from the former in nothing, but in having slenderer stalkes, yet as high, and in the flowers, which are long and hollow like them, but of a purplish colour.

Another like hereunto *Matthiolus* setteth forth with flowers onely at the toppes of the branches.

3. *Erica major floribus ex herbaceo purpureis.*
Greene Heath with purplish greene flowers.

This likewise differeth little from the last, but onely that it is lower and more largely spread, and hath darker green leaves, foure set together all along the branches, and flowers likewise up to the toppes in forme like them, but of a whitish greene purple colour being fully growne.

4. *Erica scoparia.* Brush Heath.

The Brush Heath groweth close and round, with sundry slender branches, and small greene leaves on them, which quickely fall away from the stalkes being a little dry, and the flowers two together for the most part, smaller then the former, and of an herby greene colour, but hollow as the other: besides these, it likewise sometimes beareth small scaly heads of leaves, like unto those of the common hard Time.

2. *Erica Coris folia maxima purpurascens.*
The great purple flowred Heath.

*Altera.*

5. *Erica*

3. *Erica major floribus ex herbaceo purpureis.*
Great Heath with purplish greene flowers.

4. *Erica Scoparia.*
Brush Heath.

5. *Erica pumila Belgarum Lobelij Scoparia nostras.*
The low Dutch, or our Broome Heath.

6. *Erica Scoparia altera.*
Another Broome Heath.

7. *Erica Coris folio quinta Clusij.*
*Clusius* his fifth Heath with triple branches and leaves.

8. *Erica virgata sive sexta Clusij.*
Small upright Heath without branches.

5. *Erica pumila Belgarum Lobelij scoparia nostras.*
The low *Dutch* or our Broome Heath.

This Heath groweth low and short, hard and brittle, with blackish stalkes and brownish branches, and small greene leaves like those of Tyme set on them, somewhat hairy, but foure together as in the rest, the flowers grow five or sixe together at the toppes of the branches, hollow like the rest, and of a pale purplish colour.

6. *Erica scoparia altera.*
Another Broome Heath.

This other differeth not much from the last, but in bearing three leaves at a space, somewhat broader then the other, green above and gray underneath, and a little hairy withall: the flowers likewise are many, and stand three together, at the toppes by equall distances, turning all one way, being somewhat larger and greater bellyed, but of a deeper red colour then the last.

7. *Erica Coris folio quinta Clusij.*
*Clusius* his fifth Heath, with triple branches and leaves.

This triple Heath groweth low, and with slender branches, three usually set at a joynt, and three small thinne leaves likewise set by spaces thereon, in an even order or manner, the flowers grow from the middle to the top, somewhat large, many together at the joynts, upon longer footestalkes, and are of a dull or dead purplish colour.

8. *Erica virgata sive sexta Clusij.*
Small upright Heath without branches.

This Heath hath sundry hard and upright stalkes rising from the roote, scarse a cubit high, being all single, without any branch spreading from them, and covered with an ash-coloured barke, at the severall joynts whereof come forth divers small darke greene leaves bushing together, and towards the tops sundry hollow flowers, like the rest standing together by spaces, of a most bright deepe crimson colour hanging downe,

9. *Erica similis peregrina planta Lobelij.*
*Lobel* his strange Heath.

upon

upon long footestalkes: you must understand that all these sorts beare small seede, although it is not mentioned to every one.

9. *Ericæ similis peregrina planta Lobelij.* *Lobels* strange Heath.

This strange plant (which *Lobel* could not tell what to make of, finding it growing in a pot, in *Mounsieur de Brantion* his Garden, yet would joyne it in the end of his Heathes, with this title as one of them, is a very strange Heath indeed, when as he made another plant that was very like it, to be a kinde of *Sedum minimum vermiculatum*, as in the same page, and the next line unto this, he himselfe doth set it downe, yet calling it *Erica peregrina altera*, being so neere one unto another that I thinke them *congeneres*) groweth shrubby, that is, with wooddy stalkes and branches, like other Heathes, with many small long narrow leaves upon them, and purplish flowers at the toppes, consisting of foure small leaves apeece, as neere as my memory will serve me, saith *Lobel*.

*The Place* and *Time*.

*Clusius* saith, that he found the first in sundry parts of *Portugall*, not farre from *Lisbbone*: the second in the same places, but more plentifully, and in the Country of *Narbone* as *Lobel* saith. The third also about *Lisbbone*, and the fourth both in *Spaine*, *Portugall* and *Aquitaine*, and *Narbone* also almost every where, it flowreth there twise every yeare, both in the Spring and Fall: The fifth *Clusius* saith he found, both in *Brabant* and *Gelderland*, and also in old *Castile* in *Spaine*, and *Lobel* saith in *Flanders*, and *Brabant*, but he might as well have said, on *Hampsteed Heathe*, and divers other Heathes in *England*: The sixth in *Portugall* also, and in our Land likewise. The seventh by *Lisbbone* also. The eighth was seene by *Clusius* as well in *England* about *Windsor*, in flower in *September*, as in old *Castile*, and *France*. The last was not knowne to *Lobel* from whence it came to him that had it, neither can I say more of it: They flower most of them in *Iuly* and *August*, and yet some continue in flower longer, and some beginne sooner.

*The Names*.

The first, second, third, and fourth here, are of the same numbers with *Clusius* in his history of Plants, and *Lobel* calleth the second *Inniperifolia dense fruticans Narbonensis*. The fifth is the thirteenth *Erica Coris folio* with *Clusius*, & with *Lobel Erica pumila Belgarum*, and the fifth *Erica* with *Dodonæus*. The sixth is *Clusius* his twelfth *Erica Coris folio*, which *Lobel* calleth *Erica Inniperifolia altera*. The seventh is *Clusius* his fifth *Erica coris folio*, which *Bauhinus* nameth *Erica ternis per intervalla ramulis*. The eighth is *Clusius* his sixth *Erica coris folio*, which *Lobel* calleth *Erica pumila caliculata unedonis flore*. The last is entituled by *Lobel* as I said, *Erica peregrina Brancionis*.

## CHAP. LXI.

1. *Erica procumbens sive supina pallide purpurea.* Pale purple creeping Heath.

THis leaning Heath groweth up with many round browne stalkes, of a foote long or more, leaning downe to the ground, and sometimes taking roote againe as they lye, about whom are set many long small leaves foure set together, and sometime five at a place, the flowers are of a pale purple colour, standing at the toppes of the branches like unto the other of this kinde, the seed that followeth in this as in most of the other, is small and blackish, the roote is hard and wooddy.

2. *Erica supina herbacea.* The greene flowred Heath.

This Heath hath low creeping stalkes, scarse a foote high, branched forth, and foure leaves at every place, set a crosse thereon, the flowers come forth among the leaves, towards the tops, being small and hollow, with foure ends like the rest, but of an herby or greene colour: the seede is like the other.

3. *Erica supina carnea.* Blush coloured leaning Heath.

This low Heath groweth not higher then the last, but much more beautifull in that, although the stalkes be blackish and slender, leaning to and lying on the ground, and the leaves stand by three at every space all along the branches: yet the flowers that grow at the ends of them, are of a fine flesh colour, hollow like the rest, and ending in foure points with eight blackish threds within them, and a purplish pointell in the middle; this hath also small blackish seede, this is often found with leafy greene heads like those of Time.

4. *Erica supina maritima Anglica.* Our English low Sea Heath.

4. *Erica supina maritima Anglica.* Our *English* Sea low Heath.

This fine small Heath groweth low, but thicke set with stalkes and branches, and thereon very small blewish greene leaves up to the toppes where the flowers stand many together as in others, of an excellent purple colour, continuing long in flower and colour.

*The*

*The Place* and *Time.*

The first *Clusius* found in *Styria* and *Austria*, upon the hills there, and so likewise the second, and the third in *Hungary*, and flower at the time with the rest: The last was found by *Lobel*, about *Porsmouth* in our owne Land.

*The Names.*

The first, second, and third, is the seventh, eighth, and ninth *Erica Coris folio* of *Clusius*, the last hath not beene mentioned by any before now, and by *Lobel* termed *angustifolia maritima Anglo britanica.*

## CHAP. LXII.

*Erica baccifera fructu albo.* White berryed Heathe.

THe white berryed Heath riseth up with stalkes a cubit high distributed into branches, and both covered with a blacker barke then any of the rest, the leaves likewise that are set in a triple order at every place, are of a blacker greene colour, and of a little heating as well as binding taste: it hath sundry small brave shining or transparent white berries like almost unto darke pearles, at the toppes of the branches full of an acide juyce, and three hard graines or seede within them, what flowers it bore hath not beene as yet observed.

2. *Erica baccifera nigra.* Blacke berryed Heath.

The branches of this Heathe, spread farre about upon the ground, and as they lye shoote forth rootes againe, taking up after a while, a great deale of roome, which a number of triple leaves doe compasse, and sometimes foure at every space, being thicker, somewhat like unto the former, at the first of a drying taste, and after somewhat sharpe and biting upon the tongue: the flowers stand at the joynts with the leaves, towards the toppes, consisting of three leaves a peece, of a whitish greene colour, with purplish threds within them, which turne into small blacke berries, like unto Iuniper berries, with a darke purplish juyce within them, and many triangular graines or seed within them likewise.

*The Place* and *Time.*

*Clusius* saith he onely found the first not farre from *Lisbbone* in *Portugall*, and the other on the Hills of *Austria* and *Styria*, and we may say in *England* and *Ireland* also in many places, and flower at the same time with the rest, or rather somewhat later.

*The Names.*

The first is called *Erica baccifera* by *Lobel*, and *Erica baccifera tenuifolia* by *Tabermontanus* and *Gerard*, and is the tenth *Erica coris folio* of *Clusius*, *Amatus Lusitanus* tooke it to be the *Acacalis* of *Dioscorides*, which the *Por-*

1. *Erica baccifera fructu albo.* White berryed Heath.

2. *Erica baccifera nigra.* Blacke berryed Heath.

*tingals* call *Tamarinhera*, and the fruite *Tamarinhas*. The second is the *Erica baccifera* of *Matthiolus*, which *Lobel*, *Lugdunensis*, and *Thalius* call *Erica baccifera Matthioli*, and is the eleventh *Erica coris folio* of *Clusius*: but this is not the *Vaccinia palustria Dodonæi*, before set forth, which *Lugdunensis* calleth *Erica baccifera Dodonæi*, nor the *Oxycoccum Cordi*, being all one.

*The Vertues.*

I have reserved the declaration of the Vertues of all the former, unto this place, that I might shew you them altogether. Heath is somewhat drying, and a little bitter withall, except the berryed sorts, as *Clusius* hath related by the taste of most of them. *Galen* saith it hath a digesting quality, resolving the malignity of humours, by transpiration or sweating, which a decoction of the flowers being drunke, doth performe, and thereby giveth much ease to the paines within the body, and expelleth the wormes therein also: the leaves and flowers made into a decoction is good against the sting or bitings of Serpents, and other venemous creatures, and the same being drunke warme saith *Matthiolus*, for thirty dayes together, morning and evening, doth absolutely breake the stone and drive it forth: the same also, or the destilled water of the whole plant, being drunke easeth the chollicke: the said water or the juyce of the herbe dropped into the eyes helpeth the weakenesse of the sight: *Clusius* saith that *Rondeletius* at *Mompelier* used the oyle made of the flowers of Heath with good successe against the Wolfe in the face or any other foule or fretting and eating canker spreading over the whole face: the same also doth dissolve tumours: a bathe made by decoction of the herbe and flowers is good for them to sit in, that are troubled with the stone, or with the gout, for it giveth much ease to them both: the white berryes of the Heath saith *Clusius* are brought to the markers in *Spaine*, and there sold to give to those that have hot agues, to coole the heate and quench their thirst; and besides are much desired saith hee, of women and children, to please their pallate: the hony that the Bees take from the flowers of Heath is called *mel improbum*, but we have not found any ill quality therein in our Land: onely it will be higher coloured then in those places where no Heath groweth.

## CHAP. LXIII.

*Agrifolium sive Aquifolium.* The Holly bush or tree.

Some have thought that there are divers sorts of Holly, some trees, some shrubs, some with prickly leaves, and some with smooth, but the truth is, it is but of one sort, for although it hath beene seene in divers places to grow to be a great tree, as *Gesner* in *hortis* reporteth, of divers, and of one at *Curia* thirty foote high, whose leaves were smooth and not prickly, yet no doubt but it rose from a young shoote that was prickely at the first, for while it is suffered to shoote forth sundry roddes from the roote, or before any of them groweth to be great, the leaves are prickely, but growing old as the *Ilex* doth, it looseth the prickles and becommeth smooth, and onely prickely at the end, and sometimes not. It is with us most usually a bush, and with many shootes from the roote growing slowly, unlesse the ground be not gravelly, where it most frequently is found, but more mellow and gentle; the outer barke whereof is of a sad greene colour, but it hath also another inward, which is whiter: the leaves are set on the stalkes and branches on short footestalkes, being somewhat broad, hard, thicke and long, smooth shining, and of a very fresh yellowish greene colour, cut round about the edges, into round notches or dents, and every point of them very sharpe and prickely: the flowers grow close to the stalkes, at the foote of the leaves many comming forth together round about them, and consist of foure white leaves with foure threds in the midde standing about a greene round head, with groweth to be a small red berry when it is ripe, like unto a Hawthorne berry, but with a little Crowne at the toppe which parteth into foure small triangular seede, with hard shels, and a small sweete kernell within them, abiding on all the Winter, almost in his greatest beauty: the roote groweth deepe, the wood is firme and hardly sinking in water, and of a whitish colour.

2. *Aquifolium undique echinatum.* Holly with leaves wholly prickely.

This differeth not from the ordinary sort, either in body, barke, fruite, roote, or use, onely in the leafe, which is no lesse armed with sharpe prickles, all upon as about the edges thereof.

*The Place* and *Time.*

Holly groweth in waste and untilled grounds, in divers Countries throughout the whole Land, and as I said seldome groweth with us to be a tree of any bignesse, it flowreth in *Iune*, and the berryes grow ripe, not untill the end of *October*, and then abide almost all the Winter long, being freshest at *Christmas*, the leaves doe alwayes abide greene.

*The Names.*

*Theophrastus* calleth it in Greeke ἀγρία, which *Gaza* rendereth *Aquifolia*, following *Pliny* therein, and yet he hath an *Aquifolia Ilex*, which is the *Ilex coccigera* declared before, by which name he would intimate that there is an *Ilex*, that hath dented prickly leaves, as the *Aquifolium* hath, and not that the *Aquifolium* is any kinde of *Ilex*, which beareth Acornes, and the rather in that the *Aquifolium* doth not endure such hot situations as that *Ilex* doth: some doe call it *Agrifolium*, as well as *Aquifolium*, *Lacuna* tooke it to be *Dioscorides* his second *Paliurus*, and *Guilandinus* from *Pliny*, the *Cratægus* of *Theophrastus*, *Dodonæus* saith that some called it *Ruscus sylvestris*, *Cæsalpinus* doubteth whether it may not be the *Hedera rigens* of *Pliny*, which he saith, *stat sine adminiculo*, and therefore; *sola omnium generum ob id vocata cissos*, none of these Authours shewing any prickles in the leaves of those plants they set forth. The *Italians* call it *Aquifoglio*, the *Spaniards Azebos*, the *French Houx*, and *Housson*, the *Germanes Walddistell*, and of some *Stechender Palmen*, as *Gesner* in *hortis* saith, which is *Palma aculeata*, without all reason, the *Dutch Hulst*, and we Holly, or Holme and Huluer.

*The Vertues.*

The berries are hot and dry, and of thinne parts, helping to breake winde saith *Dodonæus*, and therefore good to helpe the chollicke, for saith he, I have it from them who have made tryall of them, that tenne or twelve of the

2. *Agrifolium sive Aquifolium*
The Holly bush or tree.

2. *Aquifolium folio leui & aculeato toto.*
Holly with smooth leaves, and one all over prickely.

the berryes being taken doe purge by stoole, grosse clammy and flegmaticke humours: *Gerard* appropriateth these words to himselfe, as if he had had the relation, and yet he saith within a few lines after, that Holly beaten to pouther, and drunke doth stay fluxes and discenteryes, which are quite contrary one to another, upon a suddaine apprehension, but upon better consideration they may both stand for good that the fresh berries, by reason of their moist slipperinesse may move the belly downewards, and the berries being dryed, and thereby having lost their moisture and slipperinesse, doe then binde the belly as we have knowne by many experiences: but the barke of the tree, or the branches, is held to be much more effectuall to binde then the berries: *Matthiolus* saith that a decoction of the rootes of Holly (but saith he the barke of the roote is more powerfull) fomented on the places that have beene put out of joynt, doth helpe them much, both to mollifie and discusse the hardnesse and tumours, the places gather thereon, and helpeth also to consolidate the broken bones: some use to tie the branches with leaves upon their Bacon, and Martinmas Beefe, to keepe Rats and Mice from them by their prickles: the branches with berries, are used at *Christ tide* to decke up our houses withall, but that they should defend the house from lightening, and keepe themselves from witchcraft, is a superstition of the *Gentiles*, learned from *Pliny* saith *Matthiolus*: with the flowers of Holly saith *Pliny* from *Pithagores*, water is made ice: and againe, a staffe of the tree throwne at any beast, although it fall short by his defect, that threw it, will flye to him, as he lyeth still, by the speciall property of the tree: This I here relate, that you may understand the fond and vaine conceits of those times, which I would to God we were not even in these dayes tainted withall. The Birdlime made of the rootes of Holly, is as good as that made of Misseltoe, whereof neither is to be admitted into inward Physicke without certaine death or danger.

## CHAP. LXIV.

### *Laurus.* The Bay tree.

UNder the name of *Laurus* is described sundry sorts of plants by the ancients, as *Laurus Alexandrina*, *Chamædaphne*, *Daphnoides*, and *Laurus Tinus*, and *Taxa*, and others, whereof I meane not to entreate in this place, having spoken of them already in others, but of those trees that are properly called Bay trees, which are two. onely knowne to us in *Europe*, the one with broader, the other with a lesser leafe (and yet *Bellonius* saith, he observed five sorts in Mount *Athos* and *Greece*) where unto might be adjoyned the wilde Bay, but that I have shewed you the sorts thereof in another place, but unto them I will adde another sort of rare Indian Bay tree, lately knowne unto us.

1,2. *Laurus latifolia major & minor.* The greater and the lesser Bay tree.

3. *Laurus Americana exhorto Farnesiano cujus cortex Cassiæ Ligneæ multum assimilatur.* A strange Indian Bay tree, or *Cassia Lignea* of the West Indies.

1. *Laurus major sive latifolia.* The greater Bay tree.

This Bay groweth with us in many places. very high, spreading armes and branches reasonable well, covēred with a darke greenish barke, the leaves are somewhat broad and long, hard, full of veines, of a darke greene colour, pointed at the ends, and smelling somewhat sweete, but of a bitter taste, and alwayes abiding on the trees, the flowers grow many together, and of a whitish greene colour, after which come somewhat long and round berries, with a tough blacke skinne or covering, somewhat wrinckled, with a hard firme kernell within, parting into two parts, the roote spreadeth under the ground, and groweth deepe also: the wood is firme, smooth, and white.

2. *Laurus minor.* The lesser Bay tree.

The lesser Bay tree groweth not so high, and doth runne more into suckers or shootes, whereon grow smaller thinner, and longer leaves then of the former, yet smelling well also, the rest of the parts doe not vary much, but that the berryes be smaller and rounder.

3. *Laurus Americana cujus cortex Cassiæ ligneæ multum assimilatur.*
The strange Indian Bay tree, or *Cassia Lignea* of the West Indies.

I must needs adjoyne this strange Indian Bay tree, both for the rarity and excellency thereof, which I take out of *Tobias Aldinus* his description of some plants that grew in Cardinall *Farnesius* his Garden at *Rome*, and grew from the berries were brought from the West Indies, in that Garden of the Cardinall 1620. which were blacke rugged, like Bay berries, and somewhat long like Ollives, pointed at the end, and divers growing together in a bunch, each upon a short footestalke, it shortly grew into a great height and bignesse, the leaves were very like unto Bay leaves, or rather in a meane betweene the great Kings Bay (which I take to be that we call *Laurocerasus*) and the common Bay or the Citron tree, which being chewed, at the first are somewhat bitter, but after with a sweetnesse have some maccilaginousnesse or clammynesse in them, yet smelling like the common Bay, whose footestalke is thicker then of them, and the branches smaller and finer: but saith it is wonderfull to feele so much viscide and tough clamminesse in them, which made a doubt with some learned Herbarists, whether it were not the tree of Cinamon, or of *Cassia* or Canell, and that not by any light conjecture, for *Garzias ab orta* saith the leaves of the Canell tree are of the colour of Bay leaves, but neere the forme of the Citron tree leaves, and all Authours writing of the trees of Cinamon or Canell, say the leaves are like Bay leaves: the fruite also by *Garzias* of the Canell, is blacke and round, of the bignesse of an Hasell nut and like an Ollive. *Gomara, Carate,* and *Cieça* say that the fruite groweth in clusters or bunches, *Acosta* that the fruite is blacke and shining, when it is ripe, the maccilaginous taste also in this plant, seemeth to be in that sort of Canell is thought with us to be the true *Cassia lignea*, yea the best *Cassia* with *Dioscorides* is called *Daphnitis* which is a word derived from *Daphne* which is a Bay: but saith he, I will shew you my opinion, that we have no true Cinamon, although I have read of many that affirme our Canell to be the true Cinamon of the Auncients, yet I have saith he, many reasons a-

gainst

gainst it, which for brevity I here omit, hoping to declare them in another place.

*The Place* and *Time.*

The Bay groweth wilde naturally in divers places of *Narbone* in *France*, *Spaine*, and *Italy* and in other warme Countryes where it groweth very great, especially neere the Sea, but is wholly planted with us, or raised from sowing the berries: it flowreth in *May*, the fruite is scarse thorough ripe either in *October*, or *November*.

*The Names.*

It is called Δάφνη in Greeke, *quasi* δαφαυη *quod usta valde sonet*, for nothing doth more crackle or make a noise in the fire then it: in Latine *Laurus*: much Gentilisme might be inserted here of *Daphne*, the Daughter of *Ladon*, whom *Apollo* overtooke flying from him, and by the implored aide of her mother earth was transformed into a Bay, from whence taking a branch, he in honour of her, crowned himselfe: but under this rugged shell was hid a smoother kernell: for the Bay was a token of prophecy, and by *Apollo* is signified wisdome: that is, that wisdome doth foresee events, when the passions be overruled: as also that they wore a Garland of Bayes to be kept safe from lightening and thunder: that wisedome knoweth how to avoide the judgements of God, when foolishnesse is liable to them, and must undergoe them. The *Arabians* call it *Gaur* or *Gar*, the *Italians Lauro*, the *Spaniards Lanrerro*, the *French Lanrier*, the *Germanes Lorbeenbaum*, the *Dutch Laurusboon*, and we the Bay tree: the berryes are called in Greeke δαφνίδες, in Latine *Lauri baccæ*.

*The Vertues.*

*Galen* saith that the Bay leaves or barke doe dry and heale very much, and the berries more then the leaves: the barke of the roote is lesse sharpe and hot, but more bitter, and hath some astriction withall, whereby it is effectuall to breake the stone, and is good to open the obstructions of the Liver, Spleene, and other inward parts, as the dropsie and jaundise: the berryes are very effectuall against all venome, and poyson of venemous creatures, and the stings of Waspes, and Bees, as also against the pestilence, or other infectious diseases, and therefore is put into sundry Treakles for that purpose: they likewise procure womens courses, and if seven of the berries be taken by a woman in sore travell of childbirth, it will cause a speedy delivery, and expell the after birth also, and therefore women with child that have not gone out their time, must take heed of taking any, lest they procure an aborsement, or delivery before their time: they wonderfully helpe all cold and rheumaticke distillations, from the braine to the eyes, lungs, or other parts, and being made into an electuary with honey, they helpe the consumption, old coughes, shortnesse of breath, and thin rheumes: they likewise helpe the Meagrome, and mightily expell winde, and provoke urine, and helpe the Ventosities of the mother, and kill the wormes: the leaves worke also the like effects, and boyled in fish broth, give a fine rellish, both to meate and broth, and helpeth to warme the stomacke, and to cause digestion, without feare of casting, which taken by themselves they oftentimes provoke: a bathe of the decoction of the leaves and berries, is singular good both for women to sit in that are troubled with the mother, or the diseases thereof, or with the stoppings of their courses, or for the diseases of the bladder, paines in the bowells by winde, and stoppings of urine: a decoction likewise of equall parts of Bay berries, Cuminseede, Hyssope, Origanum, and Euphorbium with some hony, and the head bathed therewith, doth wonderfully helpe destillations and rheumes, and setleth the pallate of the mouth into its place: the oyle which is made of the berries, is very comfortable in all cold griefes of the joynts, nerves, arteries, stomacke, belly or wombe, and helpeth palsies, convulsions, crampes, aches, tremblings, and numnesse in any part, wearinesse also, and paines that come by sore travelling in wet weather, or foule wayes: all griefes and paines likewise proceeding from winde, either in the head, stomacke, backe, belly or wombe, by annoynting the parts affected therewith, and by putting some of the oyle, or boyling the berries in the decoctions for glisters, doth breake wind and ease the torments of the belly by the winde chollike wonderfully: it helpeth also the paines in the eares, either some of the oyle dropped thereinto, or a decoction of the berries being made to receive the warme fumes thereof into the eares by a funnell: the said oyle taketh away the markes of the skinne and flesh, by bruises, falls, &c. and dissolveth the congealed blood in them: it also helpeth the itch, scabs, and wheales in the skinne.

## CHAP. LXV.

### *Arbutus & Adrachne.* The Strawberry trees.

THese two trees doe both goe under one *English* name of the Strawberry tree, because they are so like one unto another, both in their growth, leafe, and fruite, that one not very well acquainted with them, may soone mistake one for another, and therefore I have thought good to put them both into one Chapter.

1. *Arbutus.* The Strawberry tree with dented leaves.

This Strawberry tree (in some places, as in Mount *Athos*, as *Bellonius* reporteth, groweth to be a tree of very great heighth and bignesse) in most other places it groweth but low, or rather like unto a shrub tree then of any bignesse, having a rugged barke on the body, and smooth or red on the young branches, and having many suckers rising from the rootes, with faire fresh greene leaves, set without order thereon, very like unto Bay leaves, but thicker, shorter, and finely dented about the edges, and without any sent, as the Bay leaves have, with a reddish middle rib in some places, but not usually so with us, and abiding on the bushes like the Bay: at the ends of the branches come forth long stalkes, with very fine white flowers set thicke together all the length of them whose brimmes are a little red or blush colour, formed like unto little bottles, or the flowers of Lilly convally, which being past, there rise in their places, severall round berryes, greene at the first, yellowish afterwards, and of an excellent reddish colour, and somewhat hoary withall being full ripe, like unto a Strawberry, but much greater in the naturall warme Countries, as great as a plumbe, but with us, and in *Ireland*, where they have beene found growing of their owne accord, no bigger then a Raspis berrie, and neere unto the same, both forme and colour, that is, like a pallide clarret Wine, of an austere taste, and having certaine small seedes within them each of them covered with a thinne skinne.

1. *Arbutus.* The Strawberry tree with dented leaves. 2. *Adrachne.* The Strawberry tree with smooth leaves.

2. *Adrachne.* The Strawberry tree with smooth leaves.

This other Strawberry tree groweth low and never seene so high as the former; but so like thereunto that it is discerned from it onely by these markes; the barke of the tree and branches is not rough or rugged, but smooth and redder by much, both in young and old branches like unto Corrall, yet *Theophrastus* saith it hath a white barke, which it is like he meaneth of the under or new barke that commeth after the old falleth away in Summer, but the *Arbutus* doth not so: the leaves are so like unto Bay leaves, being also smooth and not dented on the edges that they are onely distinguished from them by the smell, these having no sent, and the berries hereof are of a darker red colour, and somewhat more sweete, the other being a little austere or harsh, and so tasting on the tongue in the eating.

*The Place* and *Time.*

Both these sorts grow in the warme Easterne Countryes abundantly as also in *Greece*, and the Isles of the *Mediterranean* Seas, especially in *Candy*, on the hills, and among the Rockes, but the first especially in *Italy*, *Spaine*, and some parts of *France*, and hath beene of late dayes found in the West part of *Ireland*, of a reasonable bigge sise for a tree, but with smaller fruite: it flowreth not onely in *Iuly*, in the warme Countries, but at other times of the yeare also, and the fruite scarse ripeneth in a whole yeare, for I have seene a fresh branch, that was brought me with fresh sprung flowers and ripe fruite thereon likewise, so that it is usually seene both with flowers and fruite at once. The *Adrachne* is every third yeare spoyled of the outer barke, and regaineth it quickely, and keepeth the same time with the other.

*The Names.*

The first is called in Greeke κόμαρος *Comarus*, and the fruite so also by some, or μεμάκυλον *Memæcylon*, as *Dioscorides*, *Galen*, and others say, in Latine *Arbutus* & *Vnedo*, and by *Ovid Fraga montana*; some have thought that the *Arbutus* of *Dioscorides*, and *Theophrastus* were differing plants, because their descriptions were so divers, but by the judgement of the best they are both one, the other is called in Greeke ἀνδράχνη, yet the most Greeke copies have ἀνδράχνη, but because *Adrachne*, is the herbe *Portulaca*, Purslaine, which some to distinguish would call this *Portulaca arbor*, but *Pliny* findeth the fault, and therefore calleth it *Adrachne* and *Potulaca arbor*, since which *Gaza* and others have followed him therein: but the *Grecians* generally now adayes, as well as those in *Candy*, call it *Adrachla*, as *Honorius Bellus* saith: all our moderne Writers call them, by the same names, and no other then are here set downe, except *Gmilandinus* in *Papyro*, who attributeth all these names to one plant *Omarum*, *Conarum*, *Arbutus* & *Vnedo*, And it is observed that *Galen* saith in *Italy* among the vulgar, *Epimelis* was called by the name of *Vnedo*, peradventure because the flowers of *Epimelis* are very like to those of *Arbutus* or *Vnedo*, when as *Epimelis* is defined by himselfe to be another plant, differing both from *Arbutus*, *Vnedo*, or any of *Dioscorides* sorts of *Mespilus*. The *Arabians* call the *Arbutus Hatiladib*, the *Italians Albatro*, the *Spaniards Madronho*, and *Madromeiro*, the *French Arbousier*, the *Dutch* as not knowne to them have no name that I can finde, and we call them

them both the Strawberry tree, but with the ſeverall diſtinctions that I give them in their titles: yet it hath come to us from *Ireland*, by the name of the Cane Apple, with as great judgement and reaſon as many other vulgar names are.

*The Vertues.*

*Dioſcorides* and *Galen* ſay of the *Arbutus* that it is troubleſome to the ſtomacke, and breedeth head ache, and therefore adviſeth thoſe that have any paine in the head to forbeare the eating of that fruite, *Amatus Luſitanus* firſt ſetteth it downe, that the deſtilled water of the flowers and leaves of the *Arbutus* (but *Matthiolus* addeth the *os de Corde cervi* to be mixed therewith in pouther) is a ſoveraigne remedy and helpe againſt the peſtilence, and all other venome to be given preſently upon the firſt complaining of the griefe, it is aſtringent or binding, and therefore may well ſerve againſt fluxes: the properties of the other are not declared.

## CHAP. LXVI.

### *Morus.* The Mulberry tree.

THere are two or three ſorts of Mulberries as I have elſewhere ſhewed, yet I muſt ſhew you them here alſo.

1. *Morus nigra vulgaris.* The common blacke Mulberry tree.

This groweth if it be ſuffered very great and tall, otherwiſe it will be led on Arbours, or as you will have it, the body being great, and both it and the greater armes covered with a thicke rugged barke, the younger boughes and branches being ſmoother, whereon are round broad leaves ſet, pointed at the end, dented about the edges, and ſometimes gaſhed in on the edges, reſembling a Vine leafe, the bloomings or flowers are ſhort downie catkins, after which follow the fruite made of many graines ſet together greene at the firſt, red afterwards, and ſomewhat harſhe or ſowre, but blacke when they are full ripe, full of a ſweetiſh juyce, that will dye the fingers and mouth of them that gather and eate them: wherein lye divers ſmall ſeed, the roote groweth not deepe, but ſpreadeth farre, being of a yellowiſh colour.

2. *Morus alba.* The white Mulberry.

The white Mulberry groweth not to that greatneſſe, but riſeth higher, more knotty and brittle, ſpreading reaſonable well, but not ſo thicke, the leaves are like the former, but not ſo thicke ſet on the branches, nor ſo hard in handling, of a paler greene, and ſomewhat longer, and more divided with longer ſtalkes: the fruite is ſmaller and cloſer ſet together, greene and ſomewhat harſh before they are ripe, but exceeding ſweete, almoſt ready to procure loathing, when they are thorough ripe, and whitiſh, with the like ſeede as is in the former: the roote likewiſe is yellow but paler.

1. *Morus nigra vulgaris.* The common blacke Mulberry tree.

2. *Morus alba.* The white Mulberry tree.

3. *Morus*

3. *Morus Virginiana.* The *Virginian* Mulberry.

The *Virginian* Mulberry groweth quickely with us to be a very great tree, spreading many armes and branches, whereon grow faire great leaves very like the last: the fruite or berry is longer and redder than the first when it is ripe, and very pleasant also.

*The Place* and *Time.*

The two former sorts are noursed up as it were in Woods or great Orchards, in the Levant Countries to nourish their silke Wormes, where they keepe abundance, and may peradventure be naturall in some of those places; they are plentifully also noursed up in *Italy* for the same purpose: but the last as the name importeth came from *Virginia*, where it groweth hugely, with great store of great leaves and small store of fruite, but in the season with the other, which is in *Iuly* and *August*, yet the leaves of them all appeare the last of all other trees.

*The Names.*

It is called in Greek ē μορέα and συκάμινον & *Morea & Sycaminos*, in Latine *Morus*; some call the first *Morus rubra*, and others *nigra*, in our shoppes *Morus celsa quasi excelsa*, as a distinction betweene it and the bramble *Rubus*, whose berryes are called also *Mora*; but *bati* is added to know it by, the white is called *Morus alba & candida* by all: *Bellonius* saith that the *French* doe falsely call it *Sycomorus*, but we shall shew you the true *Sycomorus* by and by. The *Arabians* call it *Tut* and *Thut*, the *Italians Moro*, the *Spaniards Moras del Moral*, the *French Meurier* and *Meure*, the *Germanes Maulberbaum* and *Maulbeer*, the *Dutch Mooerbescemboom*, and we in *English* Mulberry, and Mulberry tree.

*The Vertues.*

The Mulberry is of different parts, the ripe berryes being by reason of their sweeteneſſe and slippery moisture, opening the belly, and the unripe binding it, especially when they are dryed, and are then good to stay fluxes and laskes, and the abundance of womens courses: but the barke of the roote hath a stronger purging quality, and a bitterneſſe withall, whereby it is able to kill the broad wormes in the body of men or children: the leaves and young tender toppes have a middle or temperate faculty: the ripe berries if they be taken before meate, doe make passage for the rest to follow, but if after meate, and passe not quickely away, they corrupt in the stomacke and draw the rest on to putrefaction with them, otherwise they trouble little: the juyce, or the syrope made of the juyce of the berryes, helpeth all inflammations and sores in the mouth or throate, and the *Vvula* or pallate when it is fallen downe: the juyce of the leaves is a remedy against the biting of the spider *Phalangium*, or any other Serpent, and for those that have taken *Aconite*, the leaves beaten with Vinegar is good to lay on any place that is burnt with fire: the leaves of the Vine, of the earely Figge, and of the Mulberry, boyled in raine water is good to wash the hairē, to cleare and to give it a faire colour: a decoction made of the barke and leaves is good to wash the mouth and teeth when they ake: if the roote be a little slit or cut and a small hole made in the ground next thereunto, in the harvest time it will give out a certaine juice, which being hardned; the next day is of good use to helpe the toothache, and to dissolve knots, and purge the belly: the leaves of Mulberries are said to stay bleeding in any place of the body, whether it be at the mouth or nostrils, or the bleeding of the piles, or of a wound, being bound unto the places: a branch of the tree taken when the Moone is at the full, and bound to the wrist of a womans arme whose courses come downe too abundantly, doth stay them in a short space, the leaves laid to steepe in urine doe take away the haires from skins.

## CHAP. LXVII.

*Sycomorus.* The true Sycomore or Mulberry Figge.

THere are two sorts of this Sycomore tree, the one bearing fruite out of the body, and greater armes of the tree onely, the other upon stalkes without leaves.

1. *Sycomorus sive Ficus Ægyptia.* The Sycomore of *Egipt.*

This Sycomore groweth to be a very great tree, bigger then the Mulberry tree, with great armes and branches, and thereon full of round and somewhat long leaves pointed at the ends, and dented about the edges, very like the round leaves of the Mulberry tree, but harder and rougher like Figge leaves, this beareth small figs or fruite, and no flower, and that differing from all other trees, for it thrusteth them forth from out of the very trunke or body it selfe onely, and the elder branches next to the body, and no where else, and are very like unto white or wilde Figges, and of the same bigneſſe, but much sweeter, and without any kernels therein, the whole tree and every part aboundeth with milke, if the barke be but gently wounded, for if deepe it giveth no milke at all, which maketh it to beare three or foure times every yeare, new rising out of the places where the old grew (but whereas *Theophrastus* and *Dioscorides* say, that the fruite ripeneth not, unleſſe they be scratched with iron scratchers, and that within foure daies after they will be ripe, the use in these dayes, where they grow is, that they doe ascend the trees, and with small knives, cut a small peece from the head of every fig, while they are greene, and after the poorer sort of people eate them. The wood hereof is sollid, hard and blacke, and abiding fresh, and as if it were still greene long after it is felled, neither will become dry, unleſſe it be kept under water, and therefore is fittest to make piles in Marshes, or waters.

2. *Sycomorus altera seu Ficus Cypria.* Another Sycomore or Figge of *Cyprus.*

This other Sycomore groweth to be as great as a Plummetree, or white Poplar tree, whose armes and branches are stored with broad and somewhat round leaves, like unto the Elme (which made *Dioscorides* say it was an Elme) but indeed very like unto the former: this also beareth such like fruite like Figges but smaller, even no bigger then plummes which rise both from the body, and the greater armes, but not immediately out of them, as in the former, but on certaine stalkes in branches, which rise by themselves, without any leaves with them, and are as sweete as figges, and beare also foure times every yeare, but not unleſſe they be slit, that the milke in them may come forth.

*The Place* and *Time.*

The first groweth chiefly in *Egipt*, in *Syria* also, and *Arabia*, and other the places neere thereunto: the other in

in *Cyprus*, *Caria*, *Rhodes*, and other the places neere them: they have not beene brought into *Italy* that I can learne: their Time is expressed in their descriptions.

*The Names.*

The first is called in Greeke συκόμορος and συκάμινος also by some, but not rightly as *Dioscorides* saith; in Latine also *Sycomorus*, and *Ficus Egyptia*, the *Egiptian* fig, and is the true Sycomore tree, and *Theophrastus* calleth it *Morus Ægyptia*, so called as *Galen* saith, from the likenesse of the tree and the fruite unto the Mulberry, and the Figge. *Bellonius* saith the *Egiptians* now adayes call it *Ficus Pharaonis* in their language, and some *Giumets* as the *Arabians* doe, the other is called by *Theophrastus Ficus Cypria* in *Creta*, *Matthiolus* calleth it *Sycomoro similis*, *Cordus* on *Dioscorides*, *Sycomorus in Cypro*, and *Lugdunensis* from *Rauwolfius Ficus Egyptia Dioscoridis*, *Sycomorus Græcorum*, and *Mumeitz* of the *Arabians*.

*The Vertues.*

The fruite of the Sycomore trees agree well in the belly, and maketh it soluble, but is troublesome in the stomacke, by the overmuch moisture, and giveth but little nourishment to the body: the milke that is taken from the tree, by wounding it gently, and afterwards dryed and made into Trochisces, and kept in an earthen pot, hath a property to mollifie hard tumours, to soder or close together the lippes of greene wounds, the fruite it selfe being laid plaisterwise, worketh after the same manner: the said dryed milke is good against venemous creatures and the plague, the same also easeth the paines in the head and eares, and is drunke by them that are spleneticke.

1, 2. *Sycomorus sive Ficus Ægyptia & Cypria.* The Egyptian and Syrian Mulberry Figgetree.

## CHAP. LXVIII.

### *Ficus.* The Figge tree.

THere are divers sorts of trees that are called Figge trees, very much differing in kinde one from another, I will therefore in this Chapter onely shew you the sorts of our ordinary eating Figges that grow in *Europe*, and afterwards of the rest, that have not beene declared before.

1. *Ficus sativa sive vulgaris.* The ordinary Figge tree.

This ordinary Figge in our Country in some places, I have seene as great almost, and as much spread as an Apple tree, with a grayish rugged barke on the body, and elder boughes, and greene on the younger, which are hollow or pithy in the middle, the leaves grow single on the branches, being long and large, thicke, rough, and of sad a green colour on the upperside, and whitish underneath, divided into three, but usually into five parts, yeelding a sharpe bitter, and almost exulcerating milke when they are broken, as the branches and the Figges also will doe when they are greene, the fruite breaketh out from the branches without any flower, and are both of sundry colours, of severall sizes, and ripening at contrary times of the yeare, as also with thicker or thinner skins that cover them, these that are most ordinary are white, and of a reasonable bignesse.

2. *Caprificus.* The wilde Figge tree.

This Figge tree differeth not from the former, but in growing not so great, and that the fruite is small and hard, never ripening on the trees, but falling off unripe and are nothing so sweete or pleasant as the manured, that is ripe and mellow, or soft, but like it while it is greene and hard.

3. *Ficus nigra sive præcox.* The blew Figge earely ripe.

This tree also differeth not in the growing from the former, but riseth not to that greatnesse, the fruite is also like the former, and of the same size and bignesse in *Spaine* and other places, but of a darke purple blackish colour, with an eye of blew as it were cast over them, and blackish red throughout, being not fully so lushious sweete as the ordinary white Figge is: this Figge tree beareth twice in the yeare in the warme Countries, that is, in the Spring about *Aprill*, and afterwards in the Autumne when the other are ripe: those in the Spring doe seldome ripen kindely, for want of the heate of the Sunne, and by reason of the moisture of the season, yet are they very delicious, so that they quickely both putrifie if they be kept long, and not artificially dryed, but quickely corrupt also in their stomackes that eate them, and therefore none dareth eate them, but they must drinke some Wine after them, to helpe to digest them, for if they passe not quickely out of the stomacke, but putrifie therein, they put them in danger to turne them into a feaver: and this is that kinde of great blacke Figge, that we have for the best kinde growing with us, which is usually planted against a wall, and yet will not ripen the fruite with us, untill *August*, and then will be so mellow and soft, and moist that they will be ready to fall about their fingers that handle them,

4. *Chamæficus.* The dwarfe Figge tree.

The dwarfe Figge tree groweth not much higher with us then to a mans shoulders, with slender branches bending

1 *Ficus vulgaris.* The ordinary Figge tree.

4. *Chamæficus.* The dwarfe Figge tree.

ding downewards: the fruite or Figgēs are ſmallēr, even in our Country then the laſt, but of the ſamē colour, and reaſonably well ſtored on them, this is tenderer then the other, and is uſually planted in boxes, to be removed into ſtoves for the Winter time, and ſet abroad in Summer like our Orenge trees.

*The Place* and *Time.*

The manured Figge hath beene as I ſuppoſe alwayes planted where it grew in any Country, the wild being found ſo in ſundry places, it is thought that both the other came out of *Barbary* into *Spaine*, *Italy*, and other places where they grow, and beare ripe fruite both in the Spring and *Auguſt*, or *September*, which in *Spaine* are after the gathering laid in the Sunne to dry, that they may the better be kept all the yeare after.

*The Names.*

The trēe is called in Greeke συκὴ and the fruite σῦκον, in Latine *Ficus* both tree and fruite: the wild Figge tree is called in Greeke συκὴ ἀγεία and ἐρινεὸς by *Galen* and others, in Latine *Ficus ſylveſtris*, & *Caprificus*; the unripe fruite of the manured, as alſo of the wilde kinde is called in Greeke ὄλυνθος, and in Latine *Groſſus*, but properly *Olynthus*, as well as *Groſſus* doe ſignifie the earely ripe of each ſort: the dryed Figges are called in Greeke ἰσχάδες, and of ſome καρύκῃ, as *Paulus Ægineta* and others, in Latine *Caricæ*, yet *Pliny* ſaith that *Carica* is a peculiar kinde of Figge, growing in *Syria*, ſo you ſee the word is uſed both by Greekes and Latines, the graines or ſmall kernells within the Figge is called by the Greekes κεγχρεμίδες, and by the Latines *Ficaria*, *Pliny lib.* 15. *c.* 19. calleth them *Frumenta*, the earely Figges are called in Greeke πρόδρομοι *quaſi precurſores*, in Latine *præcoæ* and *Groſſi* of ſome as is before ſaid, the branches of the tree are called *Cradæ* both in Greeke and Latine, yet *Nicander* his interpreter doth call the Figges themſelves ſo. In the Weſt Indies where it hath beene planted by the *Spaniards*, it never looſeth the leaves, God ſo providing them a remedy at all times againſt the venome of their Spiders, which is the milke comming from the tree, when the leaves are broken off. The firſt is uſually called *Ficus ſativa*, or *communis* by all; In our Summer Iſlands they grow ſo mellow, as that they will be dryed at no hand to be kept long, as thoſe in *Spaine* are (which commeth to paſſe as I thinke, for want of skill in taking them in their fit time, that is, before they grow too ripe and mellow.) The ſecond as I ſaid before is called *Ficus ſylveſtris* and *Caprificus*. The third is called *Ficus nigra*, or *purpurea*, and of ſome *Ficus de Algarva*, yet ſome doe hold that the laſt or dwarfe Fig is more truely called ſo, and ſome that they may be both called *Ficus de Algarva*: it is generally called *Chamæſicus*, or *humilis Ficus*, and *Ficus pumila* by diverſe, *Lugdunenſis* calleth it *Chamæſyce arbore*. The *Arabians* call it *Sin*, or *Fin*, or *Tin*, the *Italians Fichi*, the *Spaniards Hygos*, the *French Figues*, and the tree *Figuier*, the *Germanes Feighenbaum*, the *Dutch Feigenboom*, and we in *Engliſh* Figges, and Figge tree.

*The Vertues.*

The Figge tree is hot, and of thinne parts, which the milke that iſſueth from the leaves and branches, being broken, and the juyce taken from them, when they are young and preſſed forth, doe plainely declare, being exceeding hot, not onely biting and ſharpe, or forcibly clenſing, but even exulcerating and offending the mouthes of the veines, and taking away wartes, as alſo that it purgeth, yet is it not ſafe to take it inwardly, for feare of exulcerating inwardly, yea the branches of the tree are of ſuch an hot temper, that if they be put to boyle with

Beefe

Beefe that is hard, it will thereby become tender and ſoft, the wilde Figge tree, and the milke thereof is more effectuall then that of the manured: if the leaves of the Figge tree be rubbed over the piles, they will open againe and bleede: the Figges themſelves are hot and moiſt, and nouriſh well, the dryed better then the greene, ſo they be temperately taken, for the continuall uſe of them breed ill blood, puffe up the body with looſe fleſh, and cauſe them to become louſie; yet *Galen* ſaith that the uſe of Figges and Grapes, in his old age, above all other fruit did him leaſt harme: if they be eaten while they are freſh and greene, they looſen the belly, but doe ſomewhat trouble the ſtomacke: the dryed Figges doe heate the ſtomacke, and cauſe thirſt, yet they nouriſh and are good for the throate, and arteries, the reignes and bladder, and to regaine a good colour to them that by long ſickneſſe have loſt it: Figges are one of *Mithridates* three ingredients into his antidote, againſt both poyſon and Plague, as you have heard before in Wallnuts and Rue: the decoction of Figges, Hiſſope and Licoris, is a very good Ptiſane drinke to helpe an old cough, hoarſeneſſe and ſhortneſſe of breath, and all the diſeaſes of the breſt and lungs, and is good alſo in dropſies, and the falling ſickneſſe, and for the Quinſie alſo, a ſlit figge toſted and held to an aking tooth, doth often eaſe the paines; two or three Figges ſlit, and laid all night in *aqua vitæ*, are very good for thoſe that are purſie and ſhort winded, to take them in the morning. Figges bruiſed and applyed with Barley meale, and the pouther of Fenugrecke ſeede doe mollifie the hard tumours and kernells, under the throate and eares, and elſewhere, as alſo the hardneſſe of the Mother, and if ſome leaven and ſalt be put to them, it breaketh Plague ſores, and it may be was the ſame *Hezechias* uſed: they are mixed alſo, not as *Pliny* hath it, with χάλκε ἄνθος, *id eſt flore æris* (but with χάλκανθε *Calcantha*, that is, *Copperas*, as *Dioſcorides* hath the word being miſtaken by *Pliny*,) againſt the inveterate ſores of the legges, and all other foule running ulcers: being boyled in Wine with Wormewood, and then applyed with barly meale, are very profitably applyed to the belly of thoſe that have a dropſie: and beaten with ſalt and applyed, taketh away the itch and ſcab, and the aſhes alſo of them being made up into a ſalve and applyed, healeth kibes, and chilblaines: the dryed milke of the wild Figge tree, as well as the tame doth curdle milke like rennet, and diſſolveth it being curdled, as vinegar: this milke or the juyce taken from the young lancke branches, is moiſt fit to uſe inwardly againſt the poyſon of *Gypſum*, and the *Phalangium* Spider, but outwardly applyed it is good for many things, as put into an hollow tooth, it eaſeth the paine, the ſame mingled with the juyce of Muſtard, and dropped into the eares, eaſeth the paines, noiſe, and itch in them, and helpeth the deafeneſſe; applyed to a place bitten or ſtung, by any mad dogge or venemous creature, taketh away the paine and danger together: the ſame alſo made up with Barley meale, healeth the running ſores of the head, and likewiſe helpeth the Lepry, Morphew, the white ſcurfe, and moiſt ſcabbes, puſhes, wheales, and all other eruptions in the skinne, or diſcolourings in the face: the lye that is made of the branches of the wilde or tame Figgetree, being burnt to aſhes, after it is cleered, is accounted among cauſticke medicines: it helpeth running cankers and Gangrenes, and conſumeth Warts and Wennes, by dipping ſome Wooll or Spung therein, and dayly applying it thereto, and is ſometimes dropped into hollow Vlcers, that fret and creepe, and are full of moiſt humours, for it cleanſeth, ſodereth, and bringeth up fleſh therein, and cloſeth up the lippes thereof, like thoſe plaiſters that are applyed to greene wounds: it is likewiſe drunke by them that have the bloody flixe and old defluctions; to diſperſe alſo the congealed blood in the body, by any bruiſe or fall, adding thereto a little oyle and water; and ſo it is taken by them that have either rupture or convulſion. *Ruellius* ſaith, that if a Bull, be he never ſo mad, be tyed to a Figge tree, he will quickely become tame and gentle: and ſome have affirmed, that the Figge tree and the Bay, are not blaſted with lightning. The blew Figge is no doubt of the ſame operation with the white to all purpoſes, but the fruite commeth moſt to maturity with us, and eaten with great pleaſure with ſalt and Pepper.

---

## CHAP. LXIX.

### *Muſa arbor.* The Indian Figge or Plantaine tree.

DIvers doe make this tree (or plant, whichſoever you pleaſe to call it, in that it dyeth yearely) one of the ſorts of Dates, but very erroniouſly, for it may in my judgement be more truely referred to the Figges, as divers others doe, and therefore I thinke meeteſt to be joyned unto them. It riſeth up to the heighth of ſixe or ſeven cubits, with a ſtreight ſtemme or ſtalke, as bigge as ones thigh or arme, not wooddy at all, but of a ſoft ſubſtance, and as it were compoſed of a number of foulded leaves together, ſo that it may eaſily be cut downe with the blow of a ſword, or with a knife, with a pith like marrow within, not ſpreading any branch at all, but compaſſed about with many very large leaves, foulding themſelves as they riſe, like the leaves of the flowring Indian Reede; which when they are ſpread open at large, are each of them a fathome ſometimes or more, and uſually foure or five foote long, and two foote, or ſometimes a yard broad, hanging almoſt quite downe, with a great thicke rib running through the middle, and not cut in on the edges in any place: the lower leaves ſtill falling away being dryed, and broken off with the winde, leaving the ſtemme or ſtalke bare, untill it have attained unto above a mans height, where it buſheth forth a many the like large leaves, that are of a darke greene colour on the upperſide, and paler underneath; in the midſt whereof thruſteth forth a great long bunch of flowers; as bigge as an Eſtridge egge, of a ruſſetiſh purple colour, divided into many cluſters, each flower where- *Minor & ſapiaior.*
of ſaith one is *Lilionarciſſo major, foliorum extrema ſubſtringens colore phenicens*, after which ſucceede the fruite growing in the ſame manner in cluſters, at ſeverall ſpaces or diſtances of the great long ſtalkes, two or three hundred many times together, each whereof is long and round, in ſome places greater and ſmaller then in others, ſome a ſpan long or more (and one ſort in the Kingdome of *Congo*, is ſmaller, but better relliſhed then the ordinary, yet rare and not to be found but in very few places elſe that I can learne) ſomewhat reſembling a ſmall Cowcumber, of a firmer ſubſtance then a Figge when it is cut, and without any graine or kernell within it, having a little hollowneſſe in the middle, where it may ſeeme to be parted in twaine, and are of a darke greeniſh colour being unripe, but of a whitiſh yellow if they be ſuffered to grow to the full maturity, but many doe cut them downe before they are through ripe, and either hang them up in their houſes to ripen, or to carry to Sea to ſpend afterwards, for being gathered ripe, they will not laſt long: the outer skinne is to be pared or peeled away

before

before they are eaten, the inner substance being yellowish, and of a fine sweete taste, not suddenly to be perceived, yet I having tasted of one that Doctour *Pay* gave me, did thinke I had tasted of an Orris roote, preserved with Sugar, which peradventure was not the naturall rellish thereof, but ascititious. Vnder the stalke with fruite, hangeth downe on another stalke, a tuft of leaves, which some while after will bee another bunch of fruite, usually bearing twise, and in some places thrice every yeare: when the stalke is cut downe, some say that it yeeldeth a kinde of water like milke, both for colour and taste, some say also that the roote beareth but once or twise, or thrice at the most: but the certainety is, that it needeth to be but once planted, for that it continually sendeth forth new stalkes, as the old decay, and in some Countries are soone ripe after they spring, and will have ripe fruite, from some of the plants at all times.

*The Place* and *Time.*

This generally groweth in most Provinces of the East, as well *Egipt* and *Syria*, as the Indies; it groweth also in *Brassill*, but is planted onely in the West Indies, in *Cyprus* also it will doe reasonable well, but not so in *Candy*, but in *Spaine* or *Portugall*, as I heare, it will not beare at all. *Africa* also and *Ethiopia* wanteth it not, and as is said, hath ripe and greene fruite almost all the yeare long.

*The Names.*

It is very probable that this plant was not knowne to *Theophrastus*, unlesse it be that which *lib.* 2 *c.* 8. he saith groweth in *Cyprus* with a large leafe, and a much greater fruite, but is not savoury like the rest: and therefore *Guilandinus* refuseth it, nor yet since his time to *Dioscorides* or *Galen*, no nor to *Pliny*, unlesse as *Clusius* and others thinke, it may be his *Pala*, mentioned in his 12 Booke, and 6 Chapter, whose fruite was called *Ariena*, of a wonderfull sweetenesse, one whereof was able to satisfie foure men, the leafe thereof being three cubits long and two broad, which is somwhat likely, in that as *Garsia* saith, it is yet to this day called *Palan*, in the Country of *Malabor*, which is on this side *Ganges*, and beyond *Indus*: it is diversly called, every Country almost, giving it a peculiar name, they of *Malayo Pisan*, they of *Bengala Quelli*, in other places of the Indies *Melopalanda*, in *Malavar* also *Chincapalones*, they of St. *Thomas* Island *Abella*: it is said that some doe call one sort *Senoriyns*, and another *Cadoliyns*, the *Portugals* call them *Figos dorta* and *Figos de Cananor*, others *Ficus Martabana*, of some also *Ficus Pharaonis*, they of *Ginney*, and in the Realme of *Congo Bananas*: *Lodonicus Romanus*, and *Brocard*, who wrote the description of the Holy Land call it *Adams* Apple, whom *Cardanus*, and others doe follow, supposing it to be the fruite that *Eve* tooke and gave to *Adam*: but the very text of the Scripture convinceth that errour, for it is there said, that they sowed Figtree leaves together, to make them aprons to cover their nakednesse, when as one leafe hereof had beene sufficient. Some also as *Bauhinus* setteth it downe, call it *Dudaim*, but I thinke that name better agreeeth to the Mandrake. Of the *Arabians* *Serapio*, and *Avicen* *Manz*, *Musa*, *Amusa* and *Mauum*; of the Moores *Muz*, and *Gemez*, of some Greekes and Latines *Margraita*: they of

*Musa arbor.*
The Indian Figge or Plantaine tree.

*Musæ arboris fructus.* The fruite of the said Indian Figge or Plantaine tree.

*Brassile*

*Brassile* call the tree *Paquouere*, and the fruite *Pacova*, *Oviedus* and *Acosta* call it *Platanus*, for what cause is not knowne, unlesse the largenesse of the leaves enforced that title, but from thence I thinke hath risen the name of Plantaines, whereby our *English* in all places call them by. The *Italians*, *Spaniards*, *French*, and others follow the Latine name *Musa*, and so would I it should be called, or the Indian clusterfigge, to distinguish it from the other sorts of Figges, that they be not confounded, but not *Adams* Apple as *Gerard* doth, from the superstitious conceits of *Brocard* or others, for wee might as well follow that foolish *Franciscans* that would tranferre it to the Muses, as gratefull to them. The *Portugals* have a conceit, that if this fruite be cut either thwart or aslope, there will appeare the forme of a crosse therein, and therefore they will not cut any, but breake them all that they eate, which vaine conceit it is likely they have taken from the *Maronite* Christians, as *Linschoten* saith.

*The Vertues.*

It is generally held that no man ever tooke harme by eating the fruite hereof, onely by the much eating of them they have become loose and soluble in their bodies, but that they comfort the heart and refresh the spirits: they are also good for coughes, and hoarsenesse, and to lenifie the sharpenesse of humours, descending on the lungs: it is also profitable for those whose urine is hot and sharpe, and to provoke it being stopped, stirring up also bodily lust: but they that have any feaver or ague must forbeare them, but are good for women with childe to nourish the birth: although this may seeme to be somewhat hard of digestion to weake bodyes and stomackes, yet to stirring and able persons it is not so: the fruite being cut in the middle long wise, and dryed in the Sun, is then more delicate then a Figge: being baked in an oven, it is no lesse pleasant or boyled in broth, yet it will not abide any long boyling. The leaves being soft are commended to coole such as shall lye upon them, and keepe them temperate in the great heates: some also with good effect apply the juyce of the leaves to places burnt with fire.

## CHAP. LXX.

### *Ficus Indicus spinosus.* The prickely Indian Figge.

WE have observed two sorts of this Indian Figge, the one greater, not to be preserved a Winter in our Country without a great deale of care and conveniency for it, the other lesser, abiding reasonable well with us: they that set forth the *Peruan* History, doe say that there is two sorts of wilde, one bearing no fruite, and another so prickely, that it serveth to no use, besides the manured which beareth the graine, but with these I must declare the breeding of the *Cochenille*, which is that graine which the Dyers use, and is said to be gathered from of these plants, or one of them.

1. *Ficus Indicus spinosus major.* The greater Indian Figge.

This greater Indian Figge groweth in some parts of the West Indies to have a body or trunke as bigge as ones arme or thigh, and from thence shooteth forth his leaves, but in other places, it groweth from a leafe first set into the ground, and there shooting forth rootes, and others rising out thereof on all sides, and others out of them; and so one out of another, being formed into branches of such leaves, like unto branches of other trees, each of these leaves are very large, and as thicke as ones hand, and larger in many, beset with small sharpe, and somewhat long white prickes or thornes; dangerous if undadvisedly they be handled, but in *Europe* they are not so thicke set, nor so sharpe but in many places of the leaves, the knots or places where they stood are void: the flowers come forth at the toppe of the fruite, which is at the first like unto a leafe it selfe, and breake out on the side of the greater leaves sometimes, as well as on the tops composed of eight or twelve pale yellow leaves, set in a double row with certaine yellow threds tipt with red in the middle: after the flower is withered, yet still abiding on the head of the fruite, it groweth greater and sheweth it selfe to be long, and rounder then the leaves, and flatter at the head, and like unto a Figge, which fruite also is armed with prickes as well as the leaves, and is whitish, which is taken to be the better, or of a reddish or yellowish colour on the out side, or greenish and very red within, full of a watery substance, tasting sweete and pleasant, with diverse seedes therein, and by eating

1,2. *Ficus Indica spinosa major vel minor.* The greater or lesser prickely Indian Figge.

them will cause the urine to be tincted like blood it selfe: the roote groweth neither deepe nor farre abroad.

2. *Ficus Indicus spinosus minor.* The lesser prickely Indian Figge.

This lesser Figge groweth more often with us, from leaves as farre as I can learne, yet I have knowne it rise from the sowne seede, and never into a body or stocke like the former, and is in all the rest as like it as may be, with out any difference but onely the greatnesse, which in this is neither halfe so great or thicke, or the growth halfe so high, and this declaration may be sufficient to describe it by comparing the former discourse herewith that I doe not make a double repetition of one thing.

3. *Cochenille sive Fici Indici grana.* The Dyers graine called Cochenille.

There hath beene much doubt and many variable opinions, concerning the breeding of the Cochenille, some taking it to be the *Coccognidium verum*, others to be the *Chermes Arabum*, and that it differeth not from the *Coccus Baphicus* of the *Grecians*. *Fragosus* would seeme to know more then others, and in his third Booke and 15. Chapter, saith that they are certaine graines that grow in *Peru*, at the rootes of certaine small plants, that are like unto the common Burnet Saxifrage, cleaving to the rootes of it like wild Grapes, but is utterly erronious for *Peru*, his opinion as it seemeth being taken from *Anguilara*, and *Lacuna*, who say that there are certaine graines found in some places here with us, growing on the rootes of the Burnet Saxifrage, whose inner pulpe doth give a crimson dye, and is therefore called *Coccus radicum*, that is, the roote graine: some have taken them to be flyes, or such like covered with a small thin skin or case, and sticking under the leaves of this Indian Figge: but *Ioannes de Laet* of *Antwerpe*, in his fifth Booke and third Chapter.

*Fici ejusdem Indici fructus.* The fruite of either of the Indian Figge trees.

*page* 229. of his description of the West Indies, sheweth us the truth hereof more exactly then *Oviedus* or many other that have written thereof I thinke, and saith that besides the two wild sorts, whereof one giveth no fruite and the other so prickely that it is of no use, and the tame or manured sort that beareth fruite that is very sweete and of a most pleasant taste, and either white which is esteemed the best, or red or purple, which dyeth the hands with a blooddy colour, even as Mulberryes will doe, and being eaten coloureth the urine also into the same blooddy colour. There is saith he another sort, called by the Indians *Nochezcli Nopalli*, or *Nopall Nocheztli* which although it beareth not such like fruite, yet it is more accounted of, and husbanded with more care and diligence because it beareth that precious graine *Cochinille*, so called by the *Spaniards*, as a diminitive from the *Coccus* of the auncients, so much sought after, and used by Dyers, for the excellency of the colour: This plant loveth those places that are temperate: *Herrera* describeth the manuring and ordering thereof, and *de Laet* from him in this manner: The graine Cochenille is bred on the tree, which is called *Tuna*, in very many of the Countries of the West Indies, and new *Spaine*, which hath most thicke leaves, whereby it is encreased in those places that are open, and yet defended from the North: It is a living creature, or rather a kinde of Insect or flye, not much differing, but comming neere unto a punie or wall louse, being somewhat lesse then a flea, when it first getteth to the plant, and bred from a seed no bigger then an hand worme, and doe so loade the trees, and fill the whole Garden, that they must gather them twice every yeare from the trees, which they set in order and tend like their Vines, and free them from weedes, or what else may hurt them: the younger the trees be, the more plentifully will they beare, and the better graine, but especially it is necessary for them to cleere them from the other sorts of flyes, and no lesse keepe away their hens, who will devoure the graine: and to cleare their trees from the encrease of these other sorts of flyes, they use Foxetailes, and when they are growne full ripe, they gather them with great care, and kill them by casting cold water on them, and dry them in the shaddow, and keepe them in pots: some kill them by casting ashes amongst them, and afterwards wash them, and others choke or kill them by some other wayes: but it is the best way to kill them with cold water. But now this graine is adulterated By the Merchants, after divers manners, for there are foure sorts to be found hereof: the one giveth a colour of no great worth, as being a wilde sort and not manured: another is blacker, which groweth also of it selfe, without care or husbandry, a third is a mountainous sort called *Chichimeca*, and of a meaner regard, all which they mingle together with the fourth, that is the best and manured. The divers sorts hereof among the Merchants have severall names, according as the *Spaniards* call them: every sort according to the goodnesse hath a name whereby they know it, as *Silvester* and *Tuskediobe*, the two worst sorts, being of a blacke dull colour, yet the largest graine. *Musteko* is a gray sort, and is the most ordinary we have, but the *Golbaca*, is in colour betweene both, in fise no bigger, but in goodnesse much excelleth them all, and is not much inferiour to the *Rosetta*, which is

the

the reddest in shew, and the richest in use of all. And *Tlaxcala* giveth the best sort of graine by far. *Franciscus Zimenez*, writeth that this plant bringeth forth a certaine gumme, which doth temper the heate of the reines, and of the urine, and that the juyce or water distilled from it, is a wonderfull remedy against pestilentiall and chollericke feavers. The Chochenille or graine it selfe is held to be very cordiall, and to drive infection from the heart, for it is familiarly given both to the infected with Plague, Small poxes, or other infectious or dangerous sicknesse.

*The Place* and *Time.*

Both these sorts grow in the West Indies, the greater sort all the Indies over, from *Florida*, and the other on this side it, where the greater is not found, as being a colder Country then that the greater can live in it, and flowreth with us about the end of *May*, or in *Iune*, and the fruite ripeneth not with us kindly at all, but abideth on all the Winter, and the next Summer too, and yet will be greene on the outside, and waterish or unsavoury, although somewhat reddish within, but more red within than without, and sweete also in the naturall places.

*The Names.*

Divers Authours have given divers names unto these plants, for *Matthiolus*, *Dodonæus*, *Lacuna*, *Lobel*, *Cæsalpinus* and others call it, *Ficus Indica*, divers of the Indians that be Islanders call it *Tuna* or *Tunal*, they of *Mexico* and thereabout *Nochtli*, and as I shewed before *Nochezcli Nopalli* or *Nopall Nochezcli*, and in some places also *Cardi*, but that I thinke is by the *Spaniards*, and thereupon it was called *Cardaus Indicus*, and *Ficus Indiæ*: diverse did take it to be the *Opuntia* of *Theophrastus* and *Pliny*, but erroniously, for they both say, it is an herbe fit and sweete to be eaten, but the leaves of these are not used to be eaten, neither is it an herbe or plant, naturall to any of the nations of *Europe*, *Africke* or *Asia*, but a peculiar kinde of it selfe; but *Opuntia* is an herbe growing naturally about *Opuns*, and is usually eaten, and therefore this cannot be it but another herbe, as I have shewed in the Chapter of *Opuntia marina*, among the Sea plants: some also call it *Pala arbor Pliny*, as *Bellonius* and *Anapallus* also: The lesser sort is called by *Lobel Indorum ferrumi natrix*, and *Opuntia Ostocollos*, and by *Bauhinus Ficus Indica folio spinoso fructu minore.*

*The Vertues.*

It is said that the Indians use to lay these leaves bruised upon places that are put out of joynt, or the sinewes or Arteryes over stretched, and to helpe those that are bursten or broken to knit up the places againe: the juyce of the leaves is with good successe used in foule ulcers or sores: The vertues of the graine are set downe a little before at the end of the declaration thereof.

## CHAP. LXXI.

*Ficus Indica arcuata.*
The arched Indian Figge tree.

THis admirable tree for so it is called by many, groweth to be a great tree, and tall, spreading many armes all about, and very long which by reason of the slendernesse and length, bend downe to the ground, shooting forth certaine yellowish stringes at their ends, which as soone as they come to the ground, doe thereinto thrust themselves as strongly as the first, which againe send forth other branches after a while that they are well growne in the same manner as the first, for they also in time grow great, and spread their branches, which likewise bending downe take roote againe, and thus successively one after another, untill it hath taken up a great compasse of ground, even a mile as it is said in compasse, and made as it were a Grove or Wood from that one first tree, whereunder the Indians doe shelter themselves from the heate of the Sunne, and so prune away the under boughes, and branches that they make divers walkes and crosse wayes through these trees, leaving their branches over head as arches to passe under to and fro, and cutting out some looke holes as it were, to give light and ayre to a thousand men, and more that may be sheltered under the shaddow of this one tree, with the Suckers thereof, among so many of whom it is hard to finde out the originall or mother stocke. the leaves on the young branches are like unto Quince tree leaves, greene on the upper side, and hoary white like them underneath, wherewith Elephants are much delighted to feede, and whose branches they cut downe to give them: the fruite groweth among the branches no bigger then the end of ones thumbe, but fashioned like a Figge of

*Ficus Indica Arcuata.*
The arched Indian Figge tree.

a blood

blood red colour both within and without, somewhat sweete like unto them, but not so pleasant.

*The Place* and *Time.*

This tree groweth in divers places of the East Indies, as at *Goa, Malacca. &c.* and abideth always greene, giving ripe fruite at the time with others in that Country.

*The Names.*

This tree is mentioned first by *Q. Curtius, lib. 9.* who wrote the acts of *Alexander,* in his warres into the Indies, and by *Theophrastus* also *lib. 4. c. 5.* who lived neere that time, and calleth it *Ficus Indica,* as *Pliny* also *lib. 12. c. 5.* after him doth: *Strabo* also although hee gave it no name then, or of the admirable tree, yet hereby you may perceive that it is no new found tree in these later dayes, but knowne and written of by the Ancients. *Goropius* would draw this tree into Paradise, and make it the tree of the knowledge of good and evill, that God had planted in the midst thereof, and forbad *Adam* the eating, and of which by eating, he brought a woe on himselfe and his posterity, so bold is he to take upon him to know that which he hath no authority or proofe for, but onely led by fansie and strong conceit, about the river *Acesine,* in those parts where this groweth, and therefore Paradice must needs be there also. The *Portugals* call it *Arbor de ray,* that is the tree of rootes, and thereupon *Linschate* in his Booke figureth a tree with a number of rootes thereto, rather out of fancy then sight which *Clusius* misliked. Some doe call it *Arbor Goæ,* but of most *Ficus Indica,* and I have added *arcuata* for a difference from others.

*The Vertues.*

The fruite is good and wholesome to be eaten, but I cannot learne if ever it was applyed to cure any wound or ulcer in the body, or used in Physicke, for any disease.

## CHAP. LXXII.

### *Pyrus.* The Peare tree.

Because Peares are so like unto Figges in the outward forme of them, I thinke good to joyne them next thereunto, whereof there is both manured and wilde: the manured doe transforme themselves into so many severall fashions, colours, and tastes, that it would take up many leaves to describe them at large as they might be, for not onely every Country abroad, and beyond the Seas, have severall sorts, which we never saw or heard of, but in our owne Land also, there are so many that it is almost impossible that they should all come to one mans certaine and perticular knowledge (yet have I shewed you a many of them in my Orchard heretofore.) Of the wild sorts likewise there are

1. *Pyrus sativa.* The manured Peare tree.

2. *Pyrus sylvestris.* The wilde or Choke Peare tree.

both

both abroad and at home such variety, that a man might spend his whole time thoroughly to observe and set downe all the sorts that are knowne in other places. I will therefore endeavour but to shew you here a generall description of the tree, both tame and wilde, with some sorts that are not expressed in my former Booke.

1. *Pyrus sativa.* The manured Peare tree.

The manured Peare in generall groweth higher, but slower then the Apple tree, more upright also and not spreading the branches, and no lesse thicke, but rather greater in the bulke or body: the leaves are somewhat broader and rounder, greene above and whiter underneath then those of the Apple tree: the flowers are smaller but whiter then the Apple blossomes, and the fruite more long then round for the most part, smaller also at the stalke, and greater at the head, of many differing fashions, sizes, colours, and tastes, and times both in gathering and spending, some being greene, some russet, other yellowish or reddish, some great, others small, or long, or round, or smooth, or bunched out, and so for tastes also, sweetish or lushious, or delicate or waterish, or hard and firme, and well rellished, or not so good to be eaten raw, as baked or roasted, and some to be spent as soone as they are gathered, or soone after, being Summer fruite, others not to be spent untill the Winter be either come in, or neere or fully past; each particular to every fruite were too tedious: for this Worke being growne already so voluminous, and seeing I have shewed them in part elsewhere: The wood is smooth close and firme, and serveth for many uses, both for formes to cut these figures or the like in, and instead of wainscot in many poore mens houses, and for many other purposes.

2. *Pyrus sylvestris.* The Wilde or Choake Peare tree.

The wilde Peare tree usually groweth tall and upright, like the manured kinde, and as little spreading, but sometimes low and crooked, but fuller of branches, which maketh them the more knotty, the barke is blacker and more rugged, cleaving also in many places, and easily to be pulled off; with prickes and thornes set here and there on them, but not so thicke as in the Crab, the leaves and flowers doe little vary, but that some will have larger and others lesser leaves and flowers, which will also be a little deeper coloured then others, as the fruite being greater or smaller, and of a more or lesse harsh taste, although all have some, and the colour likewise in some is greene or darke russet, and some will be so faire, yellow and red, that they would invite any that seeth them and knoweth them not to take and taste of them, which then are so different from their expectations, being harsh and unsavoury, that they presently out with their purses and bestow this adage there on, *Non est semper fides habenda fronti*: yet this harsh unsavoury fruite, though later ripe then most of the manured sortes, by being in part mellowed with the Autumnes coldes, and the standing of their juyce being pressed forth and made into Perry, doth in time so alter his former quality of harshnesse and unsavourinesse, that it becommeth fully as cleere, and almost as pleasant as white wine: the wood hereof is harder, firmer, and closer then the former, and so more knotty also, whereby it becommeth more frangible and sooner broken.

Of the manured Peares there is a sort that although it be a good Winter fruite, sweete and well rellished, especially if they be stewed or baked, yet the tree hath thornes upon it, like unto the wild sort, this was brought as it is said from *Naples* into *Lyons*, where it is plenty, and called *Poirier d' espine*, and the fruite *Poire espine*, that is, *Pyrus sativa spinosa*, the prickely Peare. *Pyrus spinosa sativa.*

The winged Peare hath a leafe alwayes, or two sometimes, growing to the sides of it, as if it came out of the Peare, and may therefore be called *Pyrophilla*, whereof *Camerarius*, speaketh in *horto*. *Pyrus foliata.*

The Pome-peare, or Apple-peare, which is a small Peare, but round at both ends like an Apple, yet the tree is a Peare tree. *Pomipyrus.*

The Blood Peare, whose inside is red, as the outside is. *Camerarius in horto* maketh mention hereof likewise. *Pyrus sanguinea.*

The Laxative Peare which looseneth the belly being eaten. *Camerarius* there also hath this. *Pyrus Laxativa.*

The double blossomed Peare. This bore double flowers with Master *Ward*, of the Kings Granary, but whether it be alive or dead, I am not assured; nor whether it kept the forme, or did alter. *Pyrus flore duplicia.*

*Pyrus sylvestris.* The wilde Peare tree.

1. Of the wilde kinde there are the greater red Choke Peare, whose colour and property, I have shewed you in the description.
2. The smaller Choke Peare.
3. The Hedge Peare.
4. The lowsie Hedge Peare.
5. The Crow wild Peare.
6, 7. Wild Peares of *Candy*, the one they call *Achlades*, the other *Agusaga*, as *Bellonius* saith.

*The Place* and *Time.*

The manured sorts are onely planted and preserved in Orchards for the purpose, the wilde sorts being some found in our owne Woods, and planted in the Hedge-rowes of fieldes, to save the ground of their growing, and yet have as much use of them as by being abroad, the wild flowring and ripening their fruite later then the manured.

*The Names.*

The manured Peare is called in Greeke ἄπιος, and in Latine *Pirus*, and *Pyrus a fructus figura quod ad Pyramidalis similitudinem, elato in mucronem turbinetur*: The wild Peare is called ἀχράς in Greeke, by *Theophrastus*, *a privativo usu, quod non sit in usu fructus ejus ad humanum corpus*, yet *Dioscorides* saith, ἀχράς is a kind of wilde Peare of it selfe, and ὄχνη, in Latine *Pirus sylvestris*, and *Pyraster*, or *Piraster*: all peaceable ages have beene much delighted with the variety of all sorts of edible fruites, and therefore *Cato*, *Columella*, and others, but especially *Pliny* hath set downe the names of a number, as they were well knowne in his time which how our age can parallell ours unto them, I cannot tell; yet *Lugdunensis* hath in some sort endeavoured it to his *French* names, but how truely I know not, nor is it greatly materiall for us to doe, because names are often given from the place where they best grow, or from the person that first brought them into their Country, or was much delighted with them, or from some other cause or accident, which names are not so fit for one Country as another: Wee have so many in owne Land, that I never knew any one that could be possessed of all sorts, although they strove to doe it as much as in them lay, for still they were informed of some they had not: And I have declared a many of them in my former Booke. The *Arabians* call it *Humecthe*, *Cirmetre*, and *Kemetri*, the *Italians Pere*, the *Spaniards Pyras*, the *French Poires*, the *Germanes Bir Biren*, and *Piren*, the *Dutch Berre*, and we Peare.

*The Vertues.*

Peares of any good or reasonable rellish are more spent for meate then medicine, and most of them eaten raw at severall times as they be fittest to spend, or else stewed or baked, as the kinde doth best sute, and every one list to use them: the sorts also that are fittest for the purpose are dryed in ovens to keepe all the yeare, being an excellent repaste: some are preserved in Sugar, as other fruites are, and served in banquets among other sweet meates, or dryed up after they are preserved and so put among other dry candid Iunckets. The Warden is chiefly, yea onely admitted to be taken by the sicke, and aguish in that it hath no actriction therein to breede obstructions, which are the utter enemies to putrid feavers. The wilde Peares by reason of their harshnesse, are not eaten as the milder sorts are, except some good kinde stewed or baked, to serve the poore peoples dyet, the other scarse fit for the hogs to eate, and therefore are for the most part where store of them grow, beaten and pressed into a liquour which is called Perry, of especiall good use at Sea in long voyages, to mingle with their fresh water, to make it the more healthfull, or lesse offensive to those that must continually drinke water: and will after some time become so milde almost as Wine, and fit and wholesome to be drunke: The Physicall uses of them both are these: They are to be discerned best by their tastes, for according to *Galens* rule, the harsh or sowre doe coole and binde, the sweete doe nourish and warme, and those that are neither much sweete or sowre, but betweene both, have answerable qualities to their degrees: all the sweete or lushious sorts doe helpe to moove the belly downewards more or lesse, but that sort much more, which hath the name of the Laxative Peare: those that are harsh or sowre, doe on the contrary part binde the belly as much, and the leaves doe so also: those that are moist doe in some sort coole, but the harsh or wilde sorts much more, and serve well to use in all causes, where there is neede of repelling medicines, and if the wild sorts be boyled with Mushromes, it maketh them the lesse dangerous, and it is said also that the ashes of the Peare tree wood being taken in drinke, or the lye of them being drunk, doth helpe them that are like to be choked with eating Mushromes: The said Peares boyled with a little hony, doth help the stomack very much, that hath any paines or oppression therein, all sorts of them somemore or lesse: but the harsher sorts doe most coole and binde outwardly applyed: and serve well to be bound to greene wounds, to coole and stay the blood, and to helpe to heale up the wound without inflammation or further trouble: Which course *Galen* himselfe as he saith was driven to use upon an exegent not having any other thing at hand for the purpose: Wild Peares therefore in the like case doe more close up the lippes of greene wounds then the other. Perry is a drinke that whosoever useth at home being not accustomed to it, will wring them a little by the belly, and will a little force it downeward, but being more used it worketh not so at all, but rather cooleth an hot or fainting stomacke, helping the digestion being temperately taken: but at Sea by the working thereof it is made more comfortable, taking away the crudity and rawnesse of the water.

## CHAP. LXXIII.

### *Malus.* The Apple tree.

THe Apple likewise is divided into tame or manured, and wilde, the one serving for Orchards, to be tended and regarded, the other to be left to the Woods and Hedge rowes of fieldes, &c. as I did therefore with Peares in the former Chapter so I meane to deale with Apples in this, give you a generall description both of tame and wilde, and the other sorts, that is, especially the Wildings or Crabbes, which were not mentioned in my former Booke.

1. *Malus vulgaris.* The common Apple tree.

The Apple tree in generall spreadeth his armes and branches more then the Peare tree, but riseth not to that height, the leaves are somewhat round, a little long pointed towards the ends of them, and dented about the edges greene both above and below: the flowers white and a little blush coloured about the edges, consisting of five leaves, the fruite that followeth in this as in the former, is of divers sizes, formes, colours, and tastes, and likewise of variable ripening and lasting, for some will be rotten before others be ripe, and some must be spent, before others be gathered.

*Flore duplici.* The double blossomed Apple differeth from the former in nothing, but in the flowers, which are double, and that it beareth no fruite.

2. *Malus sylvestris.* The Wilding or Crabbe tree.

The Crabbe groweth somewhat like the Apple tree, but full of thornes, and thicker of branches. the flowers are alike, but the fruite is generally small and very sower, yet some more then others, which the Country people to amend, doe usually rost them at the fire, and make them their Winters junckets: whereof some are redder or whiter, or greener, or yellower then others, being seldome much regarded, or distinguished more then to make Cyder or Verdjuyce of all sorts being indifferently put together.

3. *Chamæ malus.* The dwarfe or Paradise Apple.

The Paradise Apple is also a kinde of wilde Apple, yet no Crab, for it is not grafted like the manured sorts, but as the Crab, riseth without grafting to be a tree of low stature, not much higher then a man may reach, having leaves and flowers like the former: the fruit is of a reasonable size, faire and yellowish, but light and spongy, of a bitter sweet taste, not pleasant, and will not last long but quickely shrinke and wither: the body and branches are much subject to the Canker, which will quickely eate it round and kill it, and besides will have many scabby bunches that deforme it and cause it to perish, and this as it groweth elder, for it is full of suckers, from the roote, which will be as faire and smoth, as of any other tree.

Of the manured sort there is one whose flowers are wholly white & smaller, the tree lower and the fruit smaller.

*Pomanana.* There is another which hath no kernels within the core.

Of the manured kinde, the *Holland* Pippin must be remembred, which is a flat and yellowish greene Pippin, and of as good a rellish as most of the other Pippins, and of a meane size.

Of Wildings or Crabs, there is the Towne Crab, the greater and lesser red Crab, the greater and lesser white Crab, and the small hedge Crabbe.

The

*Malus.* The Apple tree.

*Malus sylvestris.* The Wilding or Crabbe tree.

*The Place and Time.*

The better sorts of Apples are planted in Orchards, and some of the other, as the dwarfe kinde, the Wildings or Crabs grow in Woods generally, yet are planted in the hedges in many Countries of this Land to make Cyder withall, the Apples in generall flower, and bud forth leaves later then Peares, and ripen earlier or later for the most part, according to the kinde.

*The Names.*

It is called in Greeke μηλέα, and the fruite μῆλον, in Latine *Malus* and *Malum*, or *Pomus* and *Pomum*, yet *Pomum* is a generall word including the fruites of many other trees, for some would distinguish all sorts of fruites into *Pomum* and *Nacem*; but *Scaliger* saith the opinion of those Grammarians is too ridiculous: it is therefore usually called *Malus*, but yet that word likewise is referred to divers other kindes of trees, as *Malus Cydonia sive Cotonea*, *Malus Medica vel Citria*, *Malus Limonia*, *Malus Auraea seu Aurantia*, *Malus Persica*, *Malus Punica*, *Malus Arminiaca vel præcocia*, and many others, and *Pliny* numbreth *Zizypha*, and *Tuberes* among them, who reciteth the names of a number of sorts frequent with them, as he doth every where with other sorts of fruites, which to relate here were impertinent, especially to us, who can apply but very few of them to those sorts are knowne among us, and to save time to spend to better purpose. *Cornarius* taketh the *Castiana mala* which *Columella* calleth *Sestiana*, to be the *Arantia* Orenge: but *Galen* appointing the *Castiana mala* to be boyled, to give one for the head ache, did not meane the Orenge, which was neither knowne to him or in his time, nor yet is used to be boyled. The *Arabians* call it *Tusa* and *Tufalia*, the *Italians Mele*, the *Spaniards Mansanas*, the *French Pomier* and *Pome*, the *Germanes Depffell* and *Apffell*, the *Dutch Appel*, and we Apple.

*The Vertues.*

Apples in generall are cold and windy, and being of sundry tastes, *Galen* sheweth thereby how to distinguish them, for some have an austere taste, and are good for fainting stomackes and loose bellyes, others sowre good to coole and quench thirst, and some sharpe, fit to cut grosse flegme, some sweete soone distributed in the body, and as quickly passed away, yet sooner corrupting in the stomacke if they be stayed: the best sorts before they be thorough ripe, are to be avoyded; then to be rosted or scalded is the best way to take them, and a little spice or seedes mixed or cast upon them, and taken after meate, doe strengthen both stomacke and bowels, especially in those that either loathe their meate or hardly digest it, and for those that are given to casting, or have a flixe or laske; those that are not sweete, but rather a little sowre or harsh, used in that manner are fittest: Sweete Apples doe loosen the belly, and thereby drive forth the wormes that are therein: sower Apples stoppe the belly, and provoke vrine; Crabs for this purpose are the fittest: The sweete Apples, as the Pippin and Pearemaine helpe to dissolve Melancholly humours, to procure mirth and expell heavinesse, and therefore are fittest for *Confectio Alkermes*, and *Syrupus de pomis*: The leaves boyled and given to drinke in hot agues, and where the heate of the liver and stomacke causeth the lippes to breake out, and the throate to grow dry harsh and furred, is very good to wash and gargle it withall, and to drinke downe some; this may to good

purpose

purpose be used, when better things are not at hand, or cannot be had: the juyce of Crabs, eyther Verdjuyce or Cider is of singular good use in the heate and faintings of the stomacke, and against casting, to make a posset with some of it, and drinke, or take some thereof by it selfe: Cider is not onely called in the North Country Wine by those beyond Seas, but is used almost as wine in divers Countries of this Land where it is made, and as I said of Perry before, to a stomacke unacquainted with it, it will be somewhat troublesome thereto, and to the belly, yet by the often use of it, it becommeth familiar and helpefull to those that have fainting or weakenesse of the spirits and stomacke, somewhat comforting and refreshing the vitall Spirits; it is of great use at Sea in long voyages, and is more desired then Perry. The juyce of Crabs or Cider applyed with wet clothes therein, to scalded or burnt places cooleth, healeth, and draweth forth the fire: a rotten Apple applyed to eyes that are blood shotten, or enflamed with heate, or that are blacke and blew about them by any stroke or fall, and bound to all day, or all night helpeth them quickely: the distilled water of rotten Apples doth coole the heate and inflammations of sores, and is good to bathe foule and creeping ulcers, and to wash the face to take away spots, freckles, or other discolourings in the face, the destilled water of good and sound Apples, is of speciall good use to procure mirth and expell melancholly; the oyntment called *Pomatum* if it be sweete and well made doth helpe the chaps in the lips or hands, or to smooth the rough skinne of the hands or face, parched with winde or other accident, to supple and make them smooth.

## CHAP. LXXIV.

### *Malus Cydonia.* The Quince tree.

There are foure or five sorts of Quinces knowne to us in these dayes, which are as followeth.

1. *Malus Cotonea vulgaris.* Our ordinary Quince tree.

The ordinary Quince tree groweth oftentimes to the height and bignesse of a reasonable Appletree, but more usually lower and crooked, with a rough barke, spreading armes and branches farre abroad: the leaves are somewhat round and like those of the Apple tree, but thicker, harder, fuller of veines, and white on the underside, not dented at all about the edges: the flowers are large and white, sometimes dasht over with a blush: the fruite that followeth is yellow, being neere to be ripe; and covered with a white freeze or Cotton, thicke set on the younger, and growing lesse, as they grow to be thorough ripe, bunched out oftentimes in some places, some being liker an Apple, and some a Peare, of a strong heady sent, and not durable to keepe, and is sowre, harsh, and of an unpleasant taste, to eate fresh, but being scalded, rosted, baked, or preserved becommeth very pleasant.

*Malus Cotonea vulgaris.*
The ordinary Quince tree.

2. *Cydonia Lusitanica.*
The *Portugall* Quince.

The onely difference in this is in the fruite, which is of two sorts, the Apple Quince is great and yellow, seldome comming to be whole or seene without chapping, it is so pleasant being fresh gathered that it may be eaten like an Apple without offence, but dressed after any the wayes aforesaid, it is much more pleasant: the peare Quince is like the other, but not fit to be eaten raw like the former, but must bee prepared after some of the wayes before set downe, and so it will take up lesse Sugar then the *English*, because it is pleasant of it selfe.

3. *Cydonia Barbarica.*
The *Barbary* Quince.

This is like unto the last in goodnesse and pleasantnesse, but lesser in bignesse, not cleaving at all.

*Lugdunensis.* The *Lyons* Quince is a reasonable great Quince, like the *English*, but not so yellow as the *Portingall* sort.

*Brunsuisensis.* The *Brunswicke* Quince is almost round, neither like peare nor Apple.

*The Place and Time.*

The first is our *English* Quince, that best likes to grow neere ponds and water sides, and is frequent through the Land, the other have their places expressed in their titles: and flower not untill after the leaves be come forth; the fruite being ripe of the *Portugall* and *Barbary*, about the middle of *September* usually, the other later by a moneth,

*The Names.*

It is called in Greeke μηλέα κυδώνια, and in Latine *Malus Cydonia, a Cydone Cretæ oppido dicitur unde prima advecta* saith *Pliny* *Cato* first called it *Cotonea Malus*, and *Pliny* after him; *Dioscorides* and *Galen* have but two sorts, the one small and round, and the other greater but lesse usefull, called *Struthia*,

which

which as *Galen* saith is so called in *Asia*, *Columella* setteth downe three sorts, *Struthia* great ones, *Chrysomela* gold colour, and *Mustea* earely ones, but little. *Virgill* in his third *Ecclog.* calleth the *Chrysomela* a wild sort in these Verses.

*Quod potui, sylvestri ex arbore lecta*
*Aurea mala decemmisi, cras altera mittam.*

But *Pliny* hath erred very much in saying that the *Struthia* or *Struthiomela*, are small, contrary to *Dioscorides*, *Galen*, and *Columella*. The *Arabians* call it *Saffargel*, the *Italians Melocotogno*, the *Spaniards Membrillio*, and *Marmello*, and from thence is our Marmelate of Quinces called *Marmelades*, the *French Coing*, and *Pomme de coing*, the *Germanes Kutten Quittenbaum*, and the fruite *Kuttenopffell*, the *Dutch Queboom* and *Queappel*, and we Quincetree, and Quince.

*The Vertues.*

Quinces have a cold and earthy faculty in them, and by the reason of their great binding, they moisten the body lesse then other fruites, for they are cold in the first, and dry in the second degree: they are acceptable to the stomacke, but much more baked, rosted, or scalded then otherwise: yet when they are greene they helpe all sorts of flixes in man or woman, and chollericke laskes, castings, and whatsoever needeth astriction, more then any way prepared by fire, yet the Syrupe of the juyce, or the conserve, is somewhat conducible for much of the binding quality is consumed by the fire: if a little vinegar be added, it stirreth up the languishing appetite, and the stomacke given to casting, and if some spices it comforteth and strengtheneth the decaying and fainting spirits, and helpeth the liver oppreſt, that it cannot perfect the digestion, and correcteth chollour and flegme: if you would have them purging, put honey to them in stead of Sugar, and if more laxative adde for chollour Rubarbe, for flegme Turbith, for watery humours Scamony: but if more forcibly to binde, use the unripe Quinces with Roses and *Acacia*, or *Hypocisthis*, and some torrefied Rubarbe: To take of the crude juyce of Quinces is held a preservative against the force of deadly poyson, not suffering it to have any force in the body, for it hath beene often found most certaine true, that the very smell of a Quince hath taken away all the strength of the poyson of *Elleborus albus*, which Hunters make to kill wild beasts, by dipping their Arrow heads therein: it hath beene also found certaine, that if Quinces be brought into a house where Grapes are hung up to be kept dry all the yeare, they will assuredly rot with the very smell of them: If there be neede of any outward binding and cooling of any hot fluxes, the oyle of Quinces, or the other medicines that may be made thereof, are very availeable to annoynt the belly or the other parts therewith, it likewise strengtheneth the stomacke and belly, and the sinues that are loosened by sharpe humours falling on them, and restraineth immoderate sweatings: the maccilage taken from the seeds of Quinces, boyled a little in water, is very good to coole the heate, heale the sore breasts of women, who have them sore by their childrens default or otherwise: the same also with a little Sugar is good to lenefie the harshnesse and hoarsenesse of the throate, and roughnesse of the tongue: the cotton or downe of Quinces boyled in Wine and applyed to plague sores, healeth them up, and laid as a plaister made up with waxe, it bringeth haire to them that are bald, and keepeth it from falling, if it be ready to shed.

## CHAP. LXXV.

### *Malus Medica vel Citria.* The Pomecitron tree.

ALthough diverse have used this word of *Malus Medica*, to comprehend under it all the other kindes of Lemmons and Orrenges, yet I meane to distinguish them severally, and take it but for one kinde, which as the most principall, I will set in the first place and the rest to follow, whereof there hath beene observed in divers Countries, divers varieties, and their names set downe by sundry Authours, which how they doe agree together I cannot tell, so few of them having beene seene in our Land. I will therefore here shew you those few that *Clusius* hath set downe, with some others of our owne observation.

1. *Malus Citria major.* The greater Pomecitron tree.

The greater Citron tree groweth not very high, in some places but with a short crooked body, but in others not much lower then the Lemmon tree, spreading sundry great long armes and branches set with long and sharpe thornes, and faire large, and broad fresh greene leaves a little dented about the edges, with a shew of almost invisible holes in them, but lesse then the Orenge leaves have, of a very sweete sent, the flowers grow at the leaves all along the branches, being somewhat longer then those of the Orrenge, made of five thicke, whitish, purple or blush leaves with some threds in the middle, after which all the yeare long followeth fruite, for it is seldome seene without ripe fruite, and halfe ripe, and small, young and greene, and blossomes all at once: This kind beareth great and large fruite, some as great as a Muske Melon, yet others lesser, but all of them with a rugged, bunched out, and uneven yellow barke, thicker then in any of the other sorts, and with small store of sowre juyce in the middle, and somewhat great pale whitish or yellow seede with a bitter kernell lying in it, the smell of this Apple is very strong, but very comfortable to the senses.

2. *Citria malus minor sive Limonera,* The lesser Pomecitron tree.

This lesser Citron tree groweth very like the former, but the leaves are somewhat lesser and shorter, and so are the thornes also. The flowers are of a deepe blush colour, and the fruite lesser and longer then they, and no bigger then the lesser fruite of the former, the rinde also reasonable thicke and yellow, but not so rugged, having more store of sowre juyce within them, and fewer seedes.

3. *Citria malus sive Limonera prægnans.* Bigge bellyed or double Citrons.

This differeth not in the tree or any part thereof from the last, but in the fruite, which is as great as the last, and a little paler yellow on the outside, having another smaller fruite growing within it lying at the very top or head, yet not to be seene before you cut it, and is divided from the other fruite with a yellow rinde, covering the most part of it, and sticking onely to the other at the head or toppe, the greater fruite hath both juyce and seede within it, but the lesser hath no seedes, and but little or no juyce, and is more sweete then sowre: the *Spaniards* call it *Limones prennades.*

4. *Limo-*

4. *Limonera dulcis.* Sweete Limoones or Limerones.

In the fruit of this tree which the *Spaniards* as *Clusius* saith call *Limones del Emperador*, is the greatest difference from the last, which is smaller then it, but twice as big as a great Lemmon, of a deeper yellow coloured barke; and thinner by much, being full of juyce, but sweete and pleasant and may be familiarly eaten, with the rinde and all.

*Malus Medica vel Citria.*
The Pomecitron tree.

5. *Limonera acida.*

Sowre Limoones, or Limerones.

This sowre Limoone is very like this last, but somewhat bigger, more yellow rinded, and somewhat rugged, the juyce whereof is more sower then it, yet lesser then of a Lemmon.

6. *Limonera multiformis.*

Changeable Limoones or Limerones.

The fruite hereof is wholly neere unto a flesh colour, and of divers formes, some being of one and some of another fashion, not constant in any; the *Spaniards* call it *Limones de figuras.*

*The Place* and *Time.*

All these sorts of Citrons grow in *Spaine*, with those that are curious, to nourse up rare fruites, but gained from sundry places abroad; and the last from the fortunate Islands. Their time is without time, even all the yeare throughout, flowring and bearing fruite.

*The Names.*

The first and great Pomecitron, is called in Greeke μηλέα μηδικὴ, that is, *Malus medica*, *Theophrastus* saith *lib.* 1. *c.* 4. that it came first from *Media* and *Persis*, and therefore was called *Malum Medicum* and *Persicum*, and some have called it *Malum Assyrium*, others *Malum Citrium* or *Citreum*, as also *Oedromela*, and *Citromela*, and *Citrangula*: some also call it *Citrus arbor*, and some *Cedrus Theophrasti & Dioscoridis*, and some *Poncires quasi Pomacitria.* And the second is called by *Clusius Limonera*, as he saith the *Spaniards* so call the tree, and the fruite *Limones*, as they doe the rest that follow, with their other severall denominations, because both tree and fruite differ from the first or true Citron, which they call *Cidras*, the *Italians Cedri*, and *Citroni*, the *French Citrons*, the *Germanes Citrinoepffell*, the *Dutch Citreen*, and *Citreenboom*, and we in *English* the Citron, or Pomecitron tree or fruite.

*The Vertues.*

All the parts of this fruite both the outer and inner rinde, both juyce and seed are of excellent use, and of contrary effects one unto another, as some hot and dry, others cold and dry: the outer yellow rinde is very sweete in smell, very aromaticall and bitter in taste: and dryed is a very soveraigne cordiall for the heart: and an excellent antidote against venome and poyson, against the plague or any other infection: it warmeth and comforteth a cold or windy stomacke, mightily dissolving the winde, and dispersing raw cold and undigested humours therein, or in the bowels: being chewed in the mouth it amendeth an evill breath, and causeth a good one: it also helpeth digestion, and is good against melancholly: these outer rindes being preserved with Sugar, are used as a junket, more then in any physicall manner, yet are they often used in cordiall electuaries, preservatives against infection and melancholly, and other the diseases aforesaid. It also helpeth to loosen the body, and therefore there is a solitive electuary made thereof called *Electuarium de Citro solutivum*, to evacuate the bodyes, or cold flegmaticke constitutions, and may be also safely used where choller is also mixed with flegme. The inner white rinde of the fruite is almost unsavoury and without taste, and is not used in any manner of physicke, but being preserved serveth to sort with other Suckets at banquets; the sowre juyce in the middle is cold and farre surpasseth that of Lemons in the effects, although not so sharpe in taste: it is singular good in all pestilentiall and burning feavers, to restraine the venome and infection, to suppresse the violence of choller, and hot distemper of the blood, and extinguish thirst, and correcteth the ill disposition of the Liver, stirreth up an appetite, and refresheth the overspent and fainting spirits; resisteth drunkennesse, and helpeth the turnings of the Braine by the hot vapours arising thereinto, and causing a frensie or want of sleepe: the seede is the last to be spoken of, but not of the least property, for it not onely equalleth the barke, but surpasseth it in many particulars, although *Galen* and *Avicen* seeme herein to be opposite one unto another. *Galen* maketh the seede to be cold, which *Matthiolus* would excuse with diverting his intent to the juyce; and *Avicen* saying it is hot in the first degree, and dry in the second; the barke or rinde, hot in the first, and dry in the end of the second degree, the inner white substance being betweene the outer barke and the inner juyce, hot and moist in the first degree, and the acide juyce cold and dry in the third degree: these seedes are very effectuall to preserve the heart and vitall spirits, from the poyson of the Scorpion or other venemous creatures, as also against the infection of the plague, or poxes, or any other contagious disease, they kill the wormes in the stomacke, provoke womens courses, cause an aborsement, and hath a digesting quality and a drying, fit to dry up and consume moist humours, both inwardly in the body, and outwardly in any moist or running ulcers and sores, and take away the paines that come after the biting of any venemous creature: the whole fruite or the branches of the trees laid in presses, Chests, or Wardrobes, keepeth

cloath

cloath, or silke Garments from Moths and Wormes, and give them a good sent also.

## CHAP. LXXVI.

### *Limonia Malus.* The Lemmon tree.

OF Lemmons also there are divers sorts, some greater, some smaller, some with thicker, and more rugged rindes, others with smoother, some with a very sharpe and tart juyce, others with a milder.

1. *Malus Limonia acida vulgaris.* The ordinary Lemmon tree.

The Lemmon tree groweth usually great and high with great armes and slender branches armed with long greenish thornes, the leaves are long and very like unto Bay tree leaves, but dented about the edges, or like unto the Citron leaves but lesser, and full of holes like unto them also; the flowers grow after the same manner as the former, but are wholly white and as sweete: the fruite that followeth is somewhat long and round, with a paler yellow rinde then in any of those before, somewhat rugged or uneven, and not so smooth as in other sorts, and somewhat thicker also, the juyce whereof within is almost as sharpe as the next, but yet may be discerned to have the taste as it were but of an hedge fruite, and such like seede as the Citron among it, but smaller and somewhat longer, if it be heedefully marked, though they may seeme both alike.

*Limonia Malus.* The Lemmon tree.

2. *Malus Limonia acida cortice tenui.*
The thin rinded sower Lemmon.

There is no difference in the tree of this, from the former, nor in the fruite, but that it is a little bigger, the rinde of a fine pale yellow colour, smoother then the other, and much thinner also, wholly replenished with a most delicate sharpe juyce, and the like seedes among it.

3. *Malus Limonia acida fructu rotundo.*
Round Lemmons.

The tree that beareth these Lemmons, is in all things like the last, but that it hath few or no thornes at all upon it, and the fruite having a thinne rinde like it, is somewhat rounder then it, with a small crowne at the head, the juyce within being as sower altogether.

4. *Malus Limonia dulcis major.*
The greater sweete Lemmon.

This Lemmon hath this difference from the other, that it is greater then any of the former Lemmons, the rinde yellower and smooth, and the juyce within it much more sweete and pleasant, that it may be eaten as an Orrenge.

5. *Malus Limonia dulcis minor.*
The Civill Lemmon.

This Lemmon is so like the best sort of thin rinded sower Lemmons, that it is hard by the outside to know their difference, for it is of the same size, but of a little deeper coloured rinde, and the juyce within like the last, of a pleasant tart taste, that may familiarly be eaten, or rather having but little sharpe taste in it.

6. *Malus Limonia sylvestris minime.* The last wilde Lemmon tree.

This sort of Lemmon groweth wild in *Syria* and *Egipt*. *Bellonius* maketh mention of it also, that it groweth about *Cairo*, that as he saith, are no bigger then Doves or Pigeons egges.

*The Place* and *Time.*

We have had all these sorts of Lemmons brought us from *Spaine* and the Ilands at severall times, whereby we have described them unto you: and for their time it holdeth equall with the former, and the other that follow, that is, hold their leaves ever greene and beare blossomes, greene and ripe fruite all the yeare through.

*The Names.*

Neither the tree nor his fruite as it is likely, were knowne to the ancient Greekes or Latines, but it is in these dayes as in former times called *Malus Limonia*, and the fruite *Limones*. The *Spaniards* as *Clusius* sheweth, call the tree *Limera*, and the fruite *Limas*, all other nations follow the Latine, according to their dialect.

*The Vertues.*

Both the rinde and the juyce of Lemmons doe come somewhat neere unto the property of the Citron, though in a weaker degree, and in the want of the one, the other may safely be used to all the purposes before mentioned for the juyce, but the barke or rinde being thinne is seldome preserved or dryed to be used inwardly, but yet commeth somewhat neere it, if any will apply it although weaker to resist poyson, venome or infection, yet the juyce being

being sharper, cooleth more, but doth not equally resist putride humours like it: an ounce and a halfe of the juyce of unripe Lemmons drunke with a little Malmesy helpeth to clense and expell the stone out of the kidneyes and likewise killeth and driveth forth the wormes in the body of men or children: if an angell of gold, or so much weight of pure leafe gold be set to steepe in three or foure ounces of pure juyce of Lemmons for foure and twenty houres, and then taken out, or the juyce drained cleane from it, and some of it given in a cup of Wine, with a little pouther of Angelica roote unto any infected with the Plague, and dangerously sicke, (if there be any hope or likelihood of recovery) it will helpe them, the seedes of these are likewise almost as effectuall as of the Citrons, the juyce of the sweete Lemmons is neither so cooling nor so operative for any of the purposes afore mentioned. The destilled water in glasse from the inner pulpe or substance of Lemmons cleareth the skin from all freckles, spots or other markes in the face, or in any other part of the body, provoketh urine, and breaketh and expelleth the stone being drunke, and helpeth also the running scab, and killeth lice in the head, the wormes in the hands or nose, and pushes and wheales in the skinne. The juyce of Lemmons is singular good to use at Sea in long voyages, to put into their Beverage to keepe them from the Scurvy, whereto long Sea journies are much subject; as also the more abundantly to quench their thirst in those hot climates: it is no lesse usefull at home for Dyers, who spend much of it in striking sundry dainty colours which will never be well done without it.

## CHAP. LXXVII.

*Malus Arantia.* The Orenge tree.

Have likewise five sorts or rather kindes of Orrenges to shew you, which are these.

1. *Malus Arantia vulgaris.* The ordinary Orrenge tree.

The grafted or ordinary manured Orrenge tree groweth often to a very great heighth and bignesse, spreading large armes and branches with a rougher barke below, and smooth greene on the branches, yet it is also often found lesse in lesse fruitefull soiles, sparingly armed with sharpe but short thornes, the leaves are somewhat like unto those of the Lemmon, but that each leafe hath a peece of a leafe set under it, and are not dented at all about the edges, and are as full of small holes in them, as any of the former, the flowers are whitish, but of a stronger sweete sent then any of the rest, and used to many other purposes then either of the other: the fruite hereof is round, with a thicke bitter rinde, of a deepe yellowish red colour, which from it taketh the name of an Orrenge colour, having a soft white loose substance, next unto the outer coloured rinde, and a sower juyce lying mixed among small skinnes in severall parts, as in the other sorts, with such like seed also: the juyce of some is lesse sower then others; and of a taste betweene sower and sweet neere unto Wine.

*Malus Arantia vulgaris.* The ordinary Orrenge tree.

2. *Malus Arantia sylvestris.*
The wilde or Crabbe Orrenge tree.

The Crabbe Orrenge tree (as our Crabbe Apple tree) groweth wild, and is fuller of branches, and thicker set with thornes, the flowers and leaves are alike, but lesser, and the fruite is very small, and of a pale yellow colour, with a thicke rinde and little juyce or sharpe within it, but plainely tasting as a Crabbe with us, differeth from a good fruite.

3. *Malus Arantia cortice dulci eduli.*
The Apple Orrenge.

This Orrenge differeth from others not so much in the colour of the outer barke which is of a deepe gold yellowish red, but in the whole fruite, which is through cut as firme almost as an Apricocke, and yet distinguished into parts on the inside, like others, which together with the barke or rinde is to bee eaten like an Apple, the barke or rinde not being bitter or tough like the rest: the *Spaniards* call this *Naranja caxel.*

4. *Malus Arantia unico grano.*
The Orrenge without seedes.

This onely differeth from that Orrenge with the best sower juyce in having but one graine or seed in the whole juyce lying within it.

5. *Malus Arantia pumilio.*
The Dwarfe Orrenge tree.

The stocke of this dwarfe tree according to his name is low, and the branches grow thicke, well stored with leaves, but they are lesser and narrower then the other, the flowers also are many, and thicke set on the branches, which beare fruite more plentifully then the former, but is lesse then the greater sorts, yet as well coloured.

*The Place* and *Time.*

All these sorts likewise we have seene being brought us from *Spaine*, and *Portingall*, the hedge or wilde Crabbe

fruite

fruite from the hither parts of *Spaine*, and keepe time with the rest.

*The Names.*

It is thought that these Apples were knowne to the auncients who called them *Mala aurea Hesperidum*, being rare any where else, and therefore *Hercules* made it one of his taskes or labours to slay the Dragon that kept the Garden where they were, and brought them away with him: Some call them *Aurantia a cortici colore aureo*, and some *Arantia ab Arantia oppido dicta*, some *Pomum Narantium*, *Dodonæus Anarantium*, and *Lobel Malum aureum*, which name doth best suite with them for Golden Apples they are indeed: All nations call them according to the Latine, and *Clusius* saith the *Spaniards* call them *Naranjas*, and the third sort here set downe *Naranja caxel*, the *Germanes* call the Orrenge *Pomerants*, and the *French Pommes d' Orenges*. The flowers of the Orenge tree are called *Napha*, and the oyntment made of them *Unguentum ex Napha*.

*The Vertues.*

The rinde of the Orrenges are bitterer and hotter then those of Lemmons, or Citrons, and therefore doe warme a cold stomacke the more, helping to breake the winde therein, and the flegme, and after the bitternesse is taken from them by steeping them in water for sundry dayes, and then preserved either wet or dry, besides their use in banquets, they are little lesse effectuall for the strengthening of the heart and spirits, and the other qualities that Citrons have: the juyce is farre inferiour to either of them, and are fitter for meate then medicine, yet foure or five ounces of the juyce taken at a time, will drive forth putrid humours from the inner parts by sweat, and after strengthen and comfort the heart. The destilled water of the flowers, besides the odoriferous sent it hath, fit for any perfume, it is good against contagious diseases, and pestilentiall feavers, to drinke thereof at sundry times, it helpeth also the cold and moist infirmities of the mother: the oyntment that is made of the flowers is often used to annoint the stomacke to helpe the cough, and to expectorate the cold raw flegme, and to warme and comfort the other places of the bodyes.

## CHAP. LXXVIII.

*Malum Assyria vel Poma Adami. Adams* Apple.

THis tree for the most part groweth as great as the Orrenge tree, yet sometimes it is no higher then the Citron tree, and spreadeth faire great armes and branches with few, and those short thornes upon them, the leaves are faire and large, almost as great as those of the Citron or Lemmon tree, pounced with holes in the like manner, the flowers also are not much unlike, but the fruite that followeth is more like unto an Orrenge, yet two or three times bigger, pale yellow rinded, thicke, rugged or uneven, and with some rifts or chaps thereon, as if it had beene bitten, (from whence was obtruded that fond opinion unto the vulgar, for wise men would be ashamed of so ridiculous an opinion, that it was the fruite that *Adam* tasted in Paradice, and that therfore the markes should remaine upon the whole kinde ever after but thus have you three or foure trees foisted into mens conceits by irreligious cozeners, for *Adams* Apple, like to the rest of the Rellickes in the World) a Spongy substance next to it, and with an acide sweete juyce, yet not so pleasant as others, lying in parts and round seedes amongst it like the Citron, which may be eaten altogether like the Apple Orrenge as *Clusius* saith.

*Malum Assyria vel Poma Adami. Adams* Apple.

*The Place* and *Time.*

This groweth with the other sorts in sundry places of *Spaine*, among the Monasteries, or with others that are curious of rare fruites, and is in nature like the rest, ever green, and bearing flowers and fruite all the yeare long.

*The Names.*

This is called by some *Pomum*, and *Malum Assyrium*, as denoting forth the place of his originall, the more generall part *Poma Adami*, yet *Cordus* in *historia*, calleth it *Citrius altera*, the *Spaniards* as *Clusius* saith, call it *Toronjas*, and some *Zamboas*, as the *Portingals* doe, the *Italians Lomie*, and *Pomi di Adamo*, the *French Poncires* in generall.

The properties hereof are referred to the Lemmons yet having a milder juyce, and therefore not so much regarded as the others: it is by some used to kill the itch and take away the scabs, to cut one of these through the middle, and thereon to cast some fine pouther of Brimstone, being heated under the cinders, and rubbed on the parts affected afterwards.

## CHAP. LXXIX.

### *Malus Punica.* The Pomegarnet tree.

THe Pomegarnet tree is distinguished into the manured, bearing fruite, and into the wilde bearing none, each of these have likewise diversities in them: Of the manured fruite, there is both sower and sweete, and of a winy taste betweene sower and sweete, for so they are distinguished in the Countryes where they grow: the wilde kinde likewise is of two sorts, and both bearing double flowers, but one greater then another, but no fruite ever followeth them.

1. *Malus Punica sativa.* The Pomegarnet tree bearing fruite.

This Pomegarnet tree groweth not great in the warme Countries, and where it is naturall (and with us rising for the most part into sundry brownish twigges) not above seven or eight foote high, spreading into many slender branches, here and there set with thornes, and with many very faire greene shining leaves like in forme and bignesse unto the leaves of large Myrtle leaves, every one upon a small reddish footestalke: among the leaves come forth here and there, the flowers which are like bell flowers, broad at the brimmes and smaller at the bottome, being one whole leafe, divided at the toppe into five parts, of an orient red crimson colour naturally, but much paler with us, and many veines running through it, with divers threds in the middle: and standing in a brownish hollow cup, or long hard huske: the fruite is great and round with a hard smooth brownish red rinde, not very thicke, but yellowish on the inside, and a crowne at the toppe stored plentifully with a most cleare liquor or juyce like wine, either sweete or sower, or betweene both, full of seedes, inclosed in skins, and the liquour among them: sometimes this breaketh the rinde as it groweth which will cause it to rot quickely. *Cordus in historia* maketh mention of one that hath no kernell or seed within it, and doth also mention a wild kinde to grow in *Spaine*, and *Africa*, which I cannot beleeve to be any other than that wild kinde with double flowers, which followeth next to this to be described, for he maketh that which beareth fruite to have a double flower which is not so.

*Absque seminibus.*

2. *Malus Punica sylvestris major sive Balanstium majus.* The greater double blossomed Pomegarnet tree.

The great wilde Pomegarnet tree with us, groweth altogether into slender brownish branches, with some thornes among them, and shining greene leaves somewhat larger then the former, but into a shrubby low tree naturally, from the branches shoote forth flowers very double, as large as a double Province Rose, but with shorter small leaves, of an excellent bright crimson colour, tending to a silken Carnation, standing in brownish hard cups or huskes, divided into five parts: there followeth no fruite unto these.

3. *Balastium minus.* The lesser double Pomegarnet tree.

This smaller kinde differeth from the other but little, the leaves onely are of a sadder greene colour, the flowers smaller, and lesse thicke, and double, and of a sadder red Orrenge tawnie colour, set also in such like hard cups

*Malus Punica sativa.*
The manured Pomegranate tree.

*Mali Punicæ sive Granatæ fructus.*
The fruite or Pomegranates.

or

or huskes. Of one of these two double sorts, it is said that there is one that beareth white flowers, and another that hath them mixed with white and red.

*Flore albo & florevario.*

*The Place* and *Time.*

The manured kindes grow in *Spaine, Portugall, Italy,* and in other warme Countries, but with us preserved and housed with great care: and the wild kinde with much more: They flower very hardly with us, the first not untill *May,* and the other much later.

2. *Malus Punica sylvestris sive Balaustium majus.* The great double blossomed Pomegarnet tree.

*The Names.*

The Pomẽgarnet is called in Greeke ῥοιὰ and ῥοά, and by *Hippocrates* οἰδᾶς, in Latine *Malus Punica,* and *Malus Granata,* and the fruite *Malum granatum,* or *Punicum,* because it is thought that they were brought over from that part of *Africke,* where old *Carthaga* stood, into that part of *Spaine,* which is now called *Granado,* and from thence called *Granatum*: The flowers of the tame kinde as *Dioscorides* saith are called *Cytini,* yet *Pliny* maketh the flowers of the wilde kinde to be called *Cytinus,* and the flowers both of tame and wilde to he *Balaustium,* but properly as I take it, *Cytinus* is the cup, wherein the flower, as well of the tame as wilde kinde doth stand, for unto their likenesse, both the flowers and seed vessels of *Asarum,* and the seede vessels of *Hyoscyamus* are resembled, and not unto the whole flower, and *Balaustium* is generally with us taken to be only the double flowers of the wilde kind: the rinde of the fruite is called in Greeke ψίδιον and οἴδιον, and so also *Psidium* and *Sidium* in Latine but generally *Malicorium* or *Cortex granatorum*: The greater double blossomed kinde is called *Balaustium Creticum* and *Cyprium,* because it groweth in both places, and the last is called *Romanum.* The *Arabians* call it *Kuman* and *Ruman,* the *Italians Melo granata,* and *Pomogranato,* the *Spaniards Granadas* and *Romanas,* the *French Grenadier* the tree, and *Pome de Grenade,* and *Migraine* the fruite, the *Germanes Granatoepffel,* the *Dutch Granaetappel,* and we in *English* Pomegranet or Pomegarnet.

*The Vertues.*

All the sorts of Pomegarnets breed good blood, but nourish little, and are helping to the stomacke, yet those that are sweete please best, but that they somewhat heate it and breede winde, and therefore forbidden in agues, because they breede choller: the sower doe binde, and are fit for an hot fainting stomacke, and stay casting, and provoke urine, and are somewhat offensive to the teeth and gummes, in the eating: those that are of a meane or winy taste, are indifferent to each part: the seedes within the fruite, or the rinde thereof doe binde very forcibly, either the pouther or the decoction taken, and stay casting, the bloody flixe, womens courses either red or white, the spitting of blood, and the running of the reynes; it is said also that they are good for the dropsie: the flowers worke the same effects: the fruite is good against the bitings of the Sea Hare, and the bitings of the Scorpion, and stayeth the immoderate longings of women with childe, the decoction of the rinde, or seedes of the fruite, with a little Syrope put to it, is good against Cankers in the mouth, and ulcers in the privy parts, the fundament, or any other part of the body, and is good against the rupture, it helpeth also the ulcers or running sores in the eares or nose, or rheumes in the eyes, to be dropped or injected, and fastneth loose teeth, destroyeth the flat wormes in the body, and helpeth to take away wens, or the like out-growings in the flesh: with the rinde of Pomegarnets instead of Gaules, or else with the Gaules also, is made the best sort of writing incke, exceeding the ordinary, both for blackenesse and durability.

---

## CHAP. LXXX.

### *Prunus.* The Plume tree.

OF Plummes there is so great variety, as I have shewed elsewhere, that it were but *actum agere* to repeate them here againe. I will therefore give you a generall description of the tree (I meane the manured kinde, for the wilde kinde which is our Blacke thorne or Sloe, is extant in another Classis of this Worke before) and that the fruite differeth in forme, colour and taste, one from another with the best properties they are serviceable unto. Vnto the Family of the Plummes belong both Apricockes, Peaches, and Nectarins, all of them being Plummes, but of severall kindes. I will therefore place the Apricocke in this Chapter as neareſt to them, and the rest in the next Chapter following.

1. *Prunus vulgaris.* The ordinary Plumme tree.

The Plum tree for the most part riseth to be a great tall tree, whose body and armes are covered with a rugged barke, more or lesse, the younger branches being smooth in all: the leaves are somewhat long and broad, and rounder in most then those of Cherryes, yet differing much among themselves, some being longer, larger or rounder then others: the flowers are white and small, made of five leaves a peece: the fruite is very variable in forme, some being ovall, or Peare fashion, or Almond like, or round, in colour some being white or yellow, red, greene, or blacke: and in taste, some being soft and waterish, others firmer and not so moist, some sweete, some sower, and others of a meane taste betweene both, or harsh, or of a taste differing from all these, wherein is contained a small smooth flattish stone, with a white bitter kernell within it. Mr. *Tradescant* had a sort that bore doubleflowers, but perished, not long continuing with him. *Flore duplici.*

*Prunum.* The Plumme tree. *Armeniaca malus sive Præcocia.* The Apricocke tree.

2. *Malus Armeniaca sive præcocia.* The Apricocke tree.

The Apricocke tree, if it stand by it selfe as a standard tree, like other Plumme trees (which it seldome doth in our Country, for that it would hardly beare fruite in that manner) will rise to be as great as a Plumme tree, with great broad, and almost round leaves, but pointed at the ends and finely dented about the edges: the flowers are white and like the former but larger, the fruite that followeth is round, with a cleft or open furrow in the middle, somewhat like unto a Peach, of a pale yellowish colour on the outside, as well as on the inside, and a little reddish on a side in most, yet whiter in some, and of differing sizes also, some smaller or greater; of a firmer or faster close substance then any of the Plummes; a smooth flattish stone in the middle, great or little, according to the fruite, which is ripe with, or before the earlier sort of Plummes (and likely long before any of our earely sorts were knowne in former times) which was the cause of the name, and a sweete kernell within it, yet it is said there is one that hath a bitter kernell, which I have not seene.

*Nucleo amaro.*

*The Place* and *Time.*

All the sorts of them are planted, none of them growing naturally in our Country, and either in Orchards, for their private possessours, or in the Hedges, or other places of the Fields, Woods, or Parkes abroad, and flower before eyther Apple or Peare, and the Apricocke before any Plumme, by a moneth or more, and is ripe by St. *Iames* tide usually, the other sorts of Plummes comming on every one in their degree, some earlier, and some later.

*The Names.*

The Plume as it is thought is in Greeke the κοκκυμηλέα, of *Theophrastus, lib.* 4. *c.* 3. and the fruite κοκκύμηλα, in Latine *Prunus* and *Prunum*, but I much doubt of it, because beside other things, not correspondent, he saith the leaves doe alwayes abide on the tree. *Ingens Prunorum turba* saith *Pliny*, even in his time, but I thinke more then twice so many now. *Bellonius lib.* 2. *c.* 91. saith, that the *Damasco* Plummes, that he saw dryed at *Damasco*, were bigger then a Wallnut, of a firme substance, and sweete taste, a little tart, with a stone within it, rather long and flat, then thicke and round, and were deare sold even there. The Apricocke is called μηλέα ἀρμενιακὴ, πρεκόκκια and βερεκόκκια, in Latine *Chrysomela. i. e. Mala aurea, Malus Armeniaca,* and *Præcocia* by all Authours, yet some call it *Baracocca*: The Plumme is called by the *Arabians Anas, Avas,* and *Hagias*, by the *Italians Prune*, and *Succine*, by the *Spaniards Prunas, Andrinas*, and *Amexcas*, by the *French Prunier*, and *Prunes*, by the *Germanes Pflaumenboom*, by the *Dutch Pruymbonen*, and we Plummes. The Apricocke is called by the *Arabians Mex*, and *Mirmex* by the *Italians Armoniache, Moniache, Bachoce* and *Grisomele*, by the *Spaniards Albiricoques, Alvaricoques*, and *Albarchigas*, by the *French Abricot*, and *Garmaignoles*, by the *Germanes Sir Iohan Pfersich*, and by us Apricocke.

*The Vertues.*

There is much diversity in the faculty of Plummes, for some that are sweete, doe moisten the stomacke, and make

make the belly soluble; those that are sowre doe quench thirst more, and binde the belly, yet they are all in some sort cooling: the moister sort and more waterish, doe soonest corrupt in the stomacke, but the firmer doe nourish more, and offend lesse taken plentifully, and those are the fittest to be preserved and kept all the yeare: but the dryed fruite, which are sold at the Grocers, under the name of Damaske Prunes, doe somewhat loosen the belly, and being stewed are often used with the poorer sort of people, both in health and sickenesse to rellish the mouth and stomacke, to procure an appetite, and a little to open the body, allay choller, and coole the stomacke: if a purging decoction with *Sena* Rubarbe, &c. be made for them to be stewed withall, it maketh them the more purging, and the more readily to be taken by those that have weake stomackes; the leaves of the tree boyled in Wine, is good to wash and gargle the mouth and throate, to dry the fluxe of rheume to the palate, gummes, or almonds of the throate: the gumme that commeth out of the trees, is good to breake the stone, and doth serve as a glew to fasten any thing withall: the said gum or the leaves boyled in vinegar and applyed, killeth tetters, and ringwormes, The Apricocks have no use in Physicke that I know, but are wholly spent as a junket, eyther fresh and greene, or dryed preserved or candid, to sort with others, for the same purpose. Onely *Matthiolus* giveth us the use of the oyle, prest out of the kernels of the stones, as the oyle of Almonds is made, to be good against the inflamed piles or hemorrhodes, the tumours or swellings of ulcers, the hoarsenesse of the voyce, the roughnesse of the tongue and throate, and likewise the paines in the eares: five ounces saith he, of the said oyle taken with one ounce of Muscadine, driveth forth the stone, and helpeth the chollicke.

## CHAP. LXXXI.

### *Malus Persica.* The Peach tree.

THe variety of Peaches is great; whereof the Nectarin is a kinde, which because I have already declared them in my former Booke, I will onely here give you the descriptions of them in generall, and the speciall uses, as I said in the last Chapter: but hereunto I must adjoyne another strange tree of the West Indies, which *Clusius* tooke to be the *Persea* of *Theophrastus*, *Dioscorides*, *Galen*, *Pliny*, and others, which how it doth agree, you shall understand.

1. *Malus Persica vulgaris.* The ordinary Peach tree.

The Peach tree groweth not so great as the Apricocke, planted either by it selfe, or against a wall, but yet spreadeth branches reasonable well, from whence spring smaller reddish twigges, whereon are set long and narrow greene leaves, dented about the edges: the blossomes are greater then of any Plumme, and of a light purple colour, after which followeth the fruite, round, and sometimes as great as a reasonable Pippin, especially some; for some are much smaller then others, as also differing in colours and tastes, as russet, red or yellow, waterish, or firme, with a frize or cotton, all over, with a cleft therein like the Apricocke, and a rugged, furrowed great stone

*Malus Persica.* The Peach tree.

*Persea arbor.* The Laurell Peach.

within it, and a bitter kernell within the stone. It sooner waxeth old and decayeth then the Apricocke by much.

*Amygdalo persicus* The Allmond Peach.

There is another kinde of Peach, whereof *Camerarius* and *Bauhinus* in his *Matthiolus*, and *Gesner in hortis* make mention, whose kernels within the rugged stone is not bitter as others are, but sweete like an Almond.

2. *Nuci persica.* The Nectarin.

The Nectarin seldome groweth so great as the Peach, the body and elder boughes being somewhat whitish, and the younger branches very red, whereon grow long leaves, very like those of the Peach: the blossome likewise is reddish, but hath smaller and narrower leaves, and the fruite that followeth is as round and great as a small Peach, but smooth on the outside, and not rough or cottony as the Peach, nor having any cleft, of differing colours and tastes, some greene, others whitish or yellow, and some red more then others, all of them of a fast firme substance, and more delicate then the Peach, but with such a rugged stone as the Peach and a bitter kernell within it.

3. *Persia arbor Clusij.* The Laurell Peach.

This strange tree whereof *Clusius* onely first made mention, is a reasonable great tree, spreading pale greene branches, and faire stiffe greene leaves on them like unto the large Bay leaves, grayish underneath and some crosse veines running through them, sweete both in sent and taste, but a little stipticke and biting: the flowers are like those of the Bay tree, and grow many, and thicke set together in tusts, at the ends of the branches consisting of six pale coloured leaves a peece, after which come fruite, at the first greene and like a plumme, but growing ripe is long and formed like a peare, of a blacke colour and pleasant taste, having a long and round kernell within it, of the fashion of an heart, and of the taste of a Chesnut or Almond: this abideth alwayes greene, not lobsing the leaves in Winter.

*The Place* and *Time.*

The two first are familiarly noursed up in our Orchards and gardens through the Land, but from whence is their originall I cannot shew you: The last *Clusius* saith was brought forth of the West Indies, and planted in a monastery in *Spaine*, where he saith he onely saw one tree, and none any where else, yet he understood from Doctor *Tonar* at *Sivill*, that he had such another growing with him: They all flower in the Spring and fructifie in Autumne.

*The Names.*

The Peach is called in Greeke περσικὴ μηλέα and ῥοδάκινα also by some, in Latine *Malus Persica*, and *Rhodacina*, but not δωράκια, as some would have it, to be derived from *Duracina*, for *Doracia* is distinguished by *Paulus Ægineta*, from *Præcocia*, and *Armenia*, and by him made all three to be better then Peaches: neither is the Greeke *Doracia*, derived from the Latines *Duracina*, but rather *è contra*. The Nectarin is called by *Matthiolus* and *Cæsalpinus*, *Nuci persica*, because it resembleth the Wallnut in the round smooth outer rinde, and the Peach in the meate, substance and stone. *Anguilara* calleth it *Persica nux*, by the same intention, and *Pliny Nuci prunum*. The last *Clusius* maketh the question, whether it be not the *Persea* of *Theophrastus lib.4.c.2.* or no, which *Dioscorides*, *Galen*, *Pliny*, and others, doe make mention of also, and which *Theophrastus* describeth to be a great and a faire tree, and most like unto the Peare tree, both in leaves flowers and branches, but that this hath an everlasting leafe; it beareth much fruite, and is ripe at all times, the young still follow the old; the fruite is of the bignesse of a Peare, long and like an Almond, and of a greene colour, it hath a stone within it, like a Plumme, but much lesse, and of a softer substance, very sweete, thus farre *Theophrastus*. Now let me descant a little hereon, and compare them. First, the leaves of *Persea*, saith *Theophrastus*, are most like unto the leafe of the Peare tree, and this saith *Clusius*, is like unto the greatest Bay leafe, the one is almost as broad as long, and the other twice as long as broad, besides it is small pointed, the flowers of *Persea* are like the Peare tree, which are much larger then those of the Bay, and doe not grow so many together as this doth, nor at the ends of the branches like this: the fruite of *Clusius* is blace, of this greene, of that like a Peare, of this as bigge as a peare, but like an Almond, of this the stone is like a Plumme, of that like an Heart, which is round and not flat, as that plumme stone is, that hath ripe fruite onely in Autumne, this at all times of the yeare. And besides all these, which are differences sufficient to distinguish them. I doe not finde almost any plant, either herbe or tree growing in the West Indies to be like unto those that grow in *Europe*, the lesser *Asia*, or the hither part of *Africa*, and therefore by all probabilities, this of *Clusius* cannot be that of *Theophrastus*, yet this sheweth an excellent judgement in *Clusius* to referre this tree to that *Persea*, but in any judgement this *Persea* of *Theophrastus* is most likely to be some kinde of *Myrobolane*, or else some other fruite not knowne to us, It was called saith *Clusius* by them where he saw it, *Mamay*, but he was afterwards enformed by Doctor *Tonar*, that it was not *Mamay*, but called *Aguacate*, by the Indians. Some have thought this *Persea*, to be all one with the *Persica arbor*, as *Palladius* calleth it, or *Malus Persica* of *Dioscorides*. *Gaza* translating *Theophrastus* in some places, rendereth it *Persica*, and in others *Persea*, as *Pliny* in one place also confoundeth them both together, although in another he distinctly speaketh of *Persea*, and separateth it himselfe from *Persica*: but how much they differ one from another, the descriptions of both doth plainely declare to any: The Peach is called by the *Arabians Sauch* and *Chauch*, by the *Italians Persiche*, by the *Spaniards Pèxegos*, by the *French Pesches*, by the *Germans Pfersichbaum*, by the *Dutch Persehoom*, and by us Peach.

*The Vertues*

Some are of opinion that the leaves of Peaches are of a cold quality, but *Galen* sheweth that the buds and leaves have an excellent bitter quality, that if they be bruised and laid on the belly, they will kill the wormes, and so will they doe also, if they be boyled in Ale and drunke, and open the belly likewise, and also is a safe medicine to discusse humours, being dryed; and the pouther of them strewed upon fresh bleeding wounds, doth both stay their bleeding and close them up: the flowers being steeped all night in a little Wine, standing warme, strained forth in the morning, and drunke fasting, doth gently open the belly, and move it downewards, and a Syrupe made of them by reiterate infusions, as the Syrupe of Roses is made is found to worke more forceably then that of Roses, for that it provoketh vomitting, and spendeth waterish and Hydropicke humours, by the continuance thereof: the flowers condited or made into a conserve, worketh to the same effect, the gumme or rather the liquour that droppeth from the tree being wounded is given in the decoction of Coltsfoote, unto those that are

troubled

troubled with the cough or with shortnesse of breath by adding thereto some sweete wine, and putting some Saffron also therein, it is good for those that are hoarse, or have lost their voyce, helpeth all the defects of the lungs and those that vomit or spit blood. Two drammes thereof given in the juyce of Lemmons, or of Radish, is good for those that are troubled with the stone, it is said some given in Plantaine or Purslane water, stayeth the casting or spitting of blood: the kernels of the stones doe wonderfully ease the paines and wringings of the belly, through winde or sharpe humours, and are much commended to be effectuall to breake and drive forth the stone, which that they may the more powerfully worke, I commend this water unto you to drinke upon occasion, three or foure ounces at a time. Take fifty kernels of Peach stones, and an hundred of the kernels of Cherry stones, a handfull of Elder flowers, fresh or dryed, and three pints of Muscadine, set them in a closed pot, into a bed of Horse dung for ten dayes, which afterwards stilled in glasse, with a gentle fire, keepe for your use: The milke or creame of these kernells being drawne forth, with some Verven water being applyed to the forehead and temples, doth much helpe to procure rest and sleepe to sicke persons wanting it: the oyle likewise drawne from the kernels doth the same being annointed, the said oyle put into glisters doth ease the paines of the chollicke proceeding from winde, and annoynted on the lower part of the belly doth the like, and dropped into the eares easeth the paines of them, the juyce of the leaves doth the like, killeth the wormes and ulcers in them, being also annoynted on the forehead and temples; it helpeth the Megrome and other paines in the head: If the kernels be bruised and boyled in vinegar untill they become thicke, and applyed to the head, or other places that have shed the haire, and are bald it doth marvellously procure the haire to grow againe. The Peaches themselves being eaten, by reason of their sweetenesse and moisture, doe soone putrefie in the stomacke; and therefore *Galen* adviseth that they be never taken after but before meate alwaies, so shall they make the rest to passe away the more speedily with them: or else taken after, they corrupt the rest in the stomacke with themselves. The Nectarin hath a firmer substance, and a more delectable taste, for which it is most accepted, being of no use in Physicke that I know. The *Persea* is not used with any.

## CHAP. LXXXII.

### *Amygalus.* The Allmond tree.

THe Almond is so like unto the Peach in every part thereof, and yet differing from it, that I can doe no lesse then joyne it next, in a severall Chapter, and although there are sundry sorts of sweete Almonds, some great and some small, others long and some short; and a bitter kinde also, yet being in the whole surface, so like one unto another, that they can be distinguished by no other thing then the Allmond, I will onely give you one description, and shew you their differences herein, which I thinke shall be sufficient. The Allmond tree groweth greater and higher then any Peach (and is therefore usually planted by it selfe, and not against a wall, and never grafted that I have seene and knowne, that would take and abide, but is alwayes planted of a stone put into the ground, where you would have it to grow, for it hardly suffereth a transplanting) the body thereof becomming very great, whereby it sheweth to be of long continuance, spreading greater armes and smaller branches, but brittle, with long narrow leaves on them, very like unto the Peach tree: the flowers are of a paler purple colour then the Peach blossomes, and not so bitter, and the fruite very like the Peach, for the outward forme, before it be ripe, but the outer rinde is a dry skinne without any cleft in it, or edible substance under it, as the Peach hath, and the shell under it is smooth and not rugged like it, and not so thicke a kernell within, being bitter in one kinde, which are small like the *Barbery* Allmonds, and sweete in all the rest, whereof some are small, and called *Barbery* Allmonds, others long and slender, and are called *Iordan* Allmonds, and others short and broad, called *Valentia* Allmonds: it is observed that those that grow in the Isle of *Cyprus*, bend downe their heads, contrary to all in any other place.

*Amygdalus.* The Allmond tree.

*The Place* and *Time.*

They grow in all places planted, that I know, or can heare of in *Syria*, *Barbery*, *Turkie*, *Spaine*, *Italy*, and wheresoever, we have both the bitter and the sweete of that sort, that is, thicke and short, growing in many places of our Land, and blossome earlier then the Peach of any sort, and the fruite ripe also before them.

*The Names.*

It is called in Greeke ἀμυγδάλη, and the fruite ἀμυγδάλη and ἀμυγδάλον, in Latine *Amygdalus*, and the fruite *Amygdalum*, and *Amygdalium*, some thinke that *Cato*

meant

meant these by the name of *Nuces Græcæ*, but yet some doe rather referre them to the Wallnuts. *Columella* maketh mention of *Nuces Græcæ*, *Inglandes*, and *Amygdalæ*, as of three kindes. for many thinke the Almond was not knowne in *Italy* in *Cato* his time. *Pliny* out of *Theophrastus* setteth downe the way to make the bitter Allmond tree to beare sweete Allmonds, and the sweete bitter: but with such fond conceits of alterations and transmutations are the workes of the ancients according to their Gentilisme too plentifully stored, which we know is contrary to the law, that God hath set in it selfe to preserve the kinde, and although there be not onely *lusus*, but *luxus naturæ*, as it hapeneth in many things, as in the Hermaphrodite, yet that altereth not the law of nature, and notwithstanding the example of the Mule. The *Arabians* call the fruite *Iauz Kauz* and *Lauzi*, the *Italians* *Mandole*, the *Spaniards Almendres*, the *French Amandes*, the *Germanes Mandelkern*, the *Dutch Amaudel*, and we in *English* Allmonds.

*The Vertues.*

The sweete Allmonds, are the pleasanter meate, formed into many fashions as every one liketh, but the bitter are the more physicall; the sweete are hot and moist in the first degree, the bitter are drying in the second: The sweete Allmonds blanched and dryed, that they may be made into pouther, and so taken by it selfe, or with other things helpeth to binde the loosenesse of the belly: the oyle of sweete Allmonds, mixed with the fine pouther of Sugar Candy is good for the dry cough, and for hoarsenesse, to take a little at once; the said oyle drunke either alone or with some Syrupe of Marsh Mallowes, is good for those that are troubled with the stone, to ease the paines, by opening and making slippery the passages thereof: It is used also by women in Childbed after their sore travell: being mixed with oyle of Tartar, it maketh a creame called *Lac Virginis*, that clenseth the skin, and lenyfieth aha dryne sse or roughnesse, parched with the winde or otherwise: it is used also by it selfe or with other things, to annoint the stomacke for the cold: The pouther of the Allmond cakes, after the oyle is pressed from them, doth serve farre better then sope to clense the hands or skinne in any place, and to supple the parts and make them smooth: The greene fruite while they are very greene, are eaten to helpe the moist humours in the stomacke, and are eaten with pleasure by women with childe, and being preserved, are very delicate. The bitter Allmonds doe provoke urine, and womens courses, and helpe to mollifie the belly; they are good also taken with *Amylum* and Mintes, for the spitting of blood, and taken with water they are good for paines in the backe, and the inflammation in the lungs; or else taken with fine Turpintine, made into an electuary or licking medicine, with honey and milke, they are good for the obstructions of the liver, for the cough and the winde chollicke taking the quantity of a Hasell nut at a time: the oyle of bitter Almonds is effectuall to all the purposes aforesaid and doth more effectually clense the skin then that of sweete Almonds: it is also used for the noyse and deafenesse in the eares, to droppe thereof into them: the bitter Allmonds themselves beaten with oyle of Roses and Vinegar annointed on the temples, doe ease the paines in the head, and procureth sleepe and rest in hot agues, or phrensies: it doth mollefie the stiffenesse of the sinewes and joynts, and healeth the bitings of dogs and foule ulcers: if one doe eate five or sixe bitter Almonds before he fall into drinking company, it will keepe him from being overtaken more then the rest: and it is said that if they be given to a Foxe in his meate, it will kill him.

## CHAP. LXXXIII.

### *Cerasus.* The Cherry tree.

THere are as many sorts of Cherries almost as of plummes, the most whereof I have declared in my former Booke, but there are some other sorts both tall and low, that are not there mentioned, and are to be shewed in this place. And although I have there set forth, both the descriptions and figures in part of some that I doe here againe mention, both of the taller and lower sort, yet I also give you the figures of some there not set forth but described: the double repetitions being to shew the differences.

1. *Cerasus vulgaris.* The ordinary Cherry tree.

The Cherry tree riseth to a reasonable heighth and greatnesse, spreading well and somewhat thicke, the leaves are neere the plumme for forme, but somewhat longer in most, and dented about the edges: the flowers come forth two or three, or foure at the most at a place or joynt together, every one on his owne footestalke, consisting of five white leaves, with some threds in the middle, after which come round berryes, greene at the first, and red when they are through ripe, of a meane bignesse and pleasant taste, with a hard white small stone within it whose kernell is somewhat bitter, but not unpleasant. Some sorts are greater and pleasanter than others, some tart, some waterish, others firme, some red, others whiter.

2. *Cerasus Trapezautina sive Laurocerasus.* The Bay Cherry, or Cherry Bay.

Because this tree beareth berryes very like to faire great blacke Cherryes, and a stone within them, like unto a Cherry stone; I thinke it is most worthy to be referred to this stocke or kindred of the Cherryes, howsoever formerly I set it among some kindes of Bayes. It sometimes groweth to be a faire great tree, spred into many branches, but usually with us it groweth as a shrubbe, shooting forth sundry greene branches, with goodly faire shining fresh greene leaves thereon, larger then any Bay leafe, the flowers are many and whitish, growing on a long cluster like unto the *Padus Theophrasti*, here also expressed, made of five leaves a peece, but much greater then they; after which commeth the fruite, being as large as any *Flanders*, and of a very blacke shining colour very sweete, with a round stone within them, very like unto a Cherry stone, this is taken to be the *Lotus secundus Theophrasti* by *Lugdunensis*, which may very well be.

3. *Cerasus racemosa putida Padus Theophrasti dicta.* The strange long cluster Cherry.

This tree as I said, is referred to the stocke or kindred of the Cherryes, although it doe not much resemble any of them. It groweth to be a great tree, whose body and greater branches are covered with a sad coloured barke, the younger branches being greene, whereon grow somewhat broad and short leaves, harder and more crumpled then any Cherry leafe, and dented about the edges: the flowers come forth at the joynts with the leaves in a long cluster many together, like those of *Laburnum*, the Beane Trefoile, but very small, and of a downy white colour

1. *Cerasus vulgaris.*
The ordinary Cherry tree.

*Chamecerasus Alpina repens.*
The creeping dwarfe Cherry tree of the *Alpes.*

*Cerasus avium racemosa.*
The cluster birds Cherry tree.

*Chamecerasus altera & Hungarica.*
Another dwarfe Cherry, and one of *Hungary.*

*Cerasa Americana sive de Baccalaos.*
The Baccalaos, or new found Land Cherry.

2. *Cerasus Trapezuntina sive Laurocerasus.*
The Bay Cherry, or Cherry Bay.

3. *Cerasus racemosa putida Padus Theophrasti dicta.*
The strange long cluster Cherry.

4,5. *Machaleb Germanicum & Syriacas* The wild rocke Cherry of *Austria*, and perfuming Cherry of *Syria*.

*6. Chamæcerasus montana Acaris folio.*
The mountaine dwarfe Cherry.

*7. Cerasus exotica rotundifolia Indica.*
The strange or Indian Cherrie.

colour, smelling somewhat strong and sweete, after which come the fruite, which are small blacke round berryes no bigger then small pease, with little substance upon them, and very small stones within them, every one on a short footestalke, but many together in a long cluster, like the wilde cluster or birdes Cherry, of an harsh taste, and of an evill sent while it is eating. The wood also smelleth strong or not well, from whence came the name.

4. *Machaleb Germanicum.* The rocke wilde Cherry of *Austria.*

This riseth sometimes to the heighth of a reasonable tree, on the branches whereof come forth certaine knots or knobs, and Cherry tree like leaves at them but lesser, and from among them a small long greene stalke, with eight or ten white flowers thereon, hanging in a cluster, made of five leaves a peece, like unto the Cherry blossome with a long pointell in the middle, compassed with five white chives, tipt with pendents, purplish at the first, and yellow after, as sweete as Hawthorne flowers, standing in greene huskes, divided into five parts, after which come small berryes no bigger then pepper cornes, and blacke on the outside: at the ends of the branches grow such like shining greene leaves as the other dented about the edges.

5. *Machaleb Syriacum.* The perfuming Cherry of *Syria.*

This *Machaleb* of the *Arabians* doth not grow to any bignesse, but with broad short leaves like the Line tree, pointed at the ends and dented about the edges, the flowers are white, and the berryes blacke, having a small stone within them like unto a Cherry stone, but lesser, and a brownish coted kernell within them, smelling hot and sweete, yet bitter withall, which many perfumers doe use to mixe with other perfuming sweetes.

6. *Chamæcerasus montana Aceris folio.* The mountaine dwarfe Cherry.

This dwarfe plant is reckoned also to the Cherryes, having broad leaves cut in or divided at the edges, resembling those of the Maple tree: the fruite is round and red like unto a Cherry, and therefore reckoned as one, two for the most part standing together on a long stalke.

7. *Chamecerasus exotica rotundifolia Indica.* The strange or Indian Cherry.

This Exoticke Indian, hath streight slender branches, with faire and somewhat broad leaves thereon, somewhat like unto those of the Cherry tree, yet some rounder and not pointed at the ends, but all finely dented about the edges: the fruite is small and red like a dwarfe Cherry.

*The Place* and *Time.*

The first kinde is alwayes planted in Orchards, where among divers other, it taketh up a roome. The second in *Turkie*, or *Trabizond*, and planted first in *Italy*, at *Genoa*, in the Prince *Orias* Garden, where *Bellonius* first, with tedious travell found it, and was sent from *Constantinople*, to *Matthiolus* and others. The third in some gravelly grounds in *Savoy*. The fourth, fifth and last, are exprest in their titles, and the sixth in *Lombardy*: And for the most part flower, and beare their fruite about the time that others of their sort doe.

*The Names.*

The Cherry tree is called in Greeke κερασος, and the fruite κερασα, in Latine *Cerasus* and *Gerasa*. *Athenæus* writeth

writeth, and so doth *Pliny*, that the Cherry was not knowne in *Italy*, before the warre with *Mithridates* King of *Pontus*, and that *Lucius Lucullus* after he had overthrowne him, brought it from *Cerasumta* in *Pontus*, into *Italy*, and gave it the name *Cerasum*, from the place he had it. The second is called by the *Turkes Trebizon Curmasi*, that is, *Dactylus Trapezuntica*, but by *Bellonius* first, as I take it, *Laurocerasus*, and *Cerasus Trapezuntina*. *Dalechampius* tooke it to be *Lotus Africana*, but *Clusius* contesteth there-against. The third is taken by *Dalechampius* to be the *Padus* of *Theophrastus*, which *Clusius* taketh, or mistaketh rather, to be the *Cerasus avium*, or *racemosa vulgo herbariorum*, which is quite another tree, as I have shewed among the other sorts of Cherryes, and *Bauhinus* followeth him therein, making them both one. The *Burgonians* about the River of *Seine*, doe call it *Pudis*, (from whence it is likely *Dalechampius* tooke the name, to come neere to *Padus*) and take it for a kinde of wilde Cherry, as the cluster Cherry is, and in the long clustering of the flowers and fruite together very like it, and because the wood smelleth strong, the *Savoyans* call it *Putier*, as also *Cerisier blanc*, *Lugdunensis* doth much confound this with the *Guajacum Pavavinum* of *Fallopius*, taking them to be all one, as also with the *Lotus secunda* of *Dioscorides*, and the *Diospyros* of *Theophrastus*, and the *Faba Græca* of *Pliny*, without all knowledge whereof he wrote as it seemeth. It came to me out of *Italy*, by the name of *Laurus regia*, but is most usually now called *Laurocerasus*, and in *English* as it is in the title. The fourth is most likely to be the *Cerasus sylvestris* of *Tragus*, and the *Mahaleb*, or *Macaleb* of *Clusius*, and the *Petrocerasus*, or *Chamæcerasus petræa* of *Gesner*, which *Bauhinus* foulely confoundeth with *Matthiolus* his *Mahaleb*, and the *Chamæcerasus Syriaca* of *Gesner*, which is the true *Mahaleb* to be both one, when as this fifth onely is the true kinde, as the sweete smelling fruite doth plainely declare, besides the diversity of the tree, as is before declared. The sixt came as a rarity from the Indies, whereof no more can as yet be said. The last is onely remembred by *Gesner* in *hortis*, and by *Lugdunensis*, who saith that *Gesner* sent a branch thereof to *Dalechampius*, by the name of *Chamæcerasus montis Generosi*. The *Arabians* call the Cherry, *Sarasie*, the *Italians Ciregie*, the *Spaniards Cerazas*, and *Guindas*, the *French Cerises*, and *Guines*, the *Germanes Kirsen*, and *Kirschen*, the *Dutch Kriken*, And we in *English* Cherry.

*The Vertues.*

Cherryes as they are of divers tastes, so they are of divers qualities, the sweete are more lubricke, and passe through the stomacke and belly more speedily, but are of little nourishment, the tart or sowre are more pleasing to an hot stomacke, and procure an appetite to meate, and helpe to cut tough flegme, and grosse humours, but when these are dryed, they are more binding the belly then being fresh, and doe give a fine rellish to broths and drinkes wherein they are boyled; being cooling in hot diseases, and welcome to the stomacke, and provoke urine; The Gum of the Cherry tree dissolved in Wine, is good for a cold cough, and hoarsenesse of the throate: helpeth to give one a better colour in the face. sharpeneth the eye-sight, stirreth up an appetite, and helpeth to breake and expell the stoue: the blacke Cherryes being bruised with the stones and distilled, the water thereof is much used to breake the stone, expell the gravell, and breake the winde: the true *Mahaleb* of *Syria*, was mistaken by *Serapio* to be the *Phyllyrea* of *Dioscorides*, when as the properties are much differing, for *Mahaleb* doth heate and mollifie, even by the testimony of *Mesues* and *Rasis*, and as *Avicen* saith, doth clense, attenuate and resolve and ease paines: The oyle drawne from the kernels, doth much more ease the paines in the bowels and backe, being annoynted, then the kernels themselves which some use for the said purpose, and for soundings, and faintings, to be taken with Mede or honyed water, and doe helpe the chollicke and stone in the kidneyes, kill the wormes in the belly, and provoke urine also.

## CHAP. LXXXIV.

### *Cornus*, The Cornell tree.

THE Cornell is divided into male and female; the male is of two sorts, one bearing red berryes like Cherries, and another whitish: the female hath no diversity.

1. *Cornus mas fructu rubro.* The male red Cornell tree.

The Cornell or Cornellian Cherry tree groweth to be a reasonable tall and great tree, the body and branches are covered with a rugged barke, and the younger smooth, whereon grow smooth leaves, and plaine, not dented at all about the edges, the flowers are many small yellow tufts, as it were short threds set together, which come forth before any leafe, and so fall away likewise, before the leaves appeare much open: the fruite are somewhat long round berries, of the bignesse of small Ollives, with a small hard stone within them, like unto an Ollive stone, reddish when they are ripe, somewhat like a Cherry, of a reasonable pleasant taste, somewhat austere withall: the wood is hard like an horne, and groweth slowly. Of this kinde *Clusius* maketh another sort, with redder berries, little differing in any thing else: and another that groweth low, but yet hath beene observed upon the transplanting to grow much greater.

*Fructu magis rubro humilis.*

2 *Cornus mas fructu albo.* The white male Cornell tree.

This other Cornell differeth not from the first in any other more notable matter then in the fruit, which becommeth not so red, but whitish when it is ripe.

3. *Cornus fœmina*, The Dogge berry or Gattēn tree.

This never riseth to be a tree of any bulke or body with us (but *Clusius* saith that he saw in the Woods of *Austria*, as bigge trees hereof as of the male, and *Bellonius* saith the same *lib.* 1. *c.* 56) but usually abideth as an hedge bush with many pithy strong twiggy stemmes rising from the roote, of a brownish colour and the sprigges more reddish, with a pith within them like unto Elder, having leaves thereon somewhat like the former, but a little shorter and broader, standing upon reddish footestalke, and the middle rib reddish likewise, the flowers are white and stand at the end of the branches, many growing together in a tuft or umbell, upon reddish footestalkes which turne into small berries, green at the first, and shining blacke when they are ripe, of a most unpleasant bitter taste provoking casting.

*The Place* and *Time.*

The first is found wild in many places of *Germany*, and the other sorts hereof also, but thē second is more rare

1. *Cornus mas fructu rubro.*
The male red Cornell tree.

3. *Cornus fœmina.*
The Dogge berry or Gatter tree.

rarē, the last growēth in every Country of the Land, serving for a hedge bush; the first flowreth very earely, as is before said, in *March*, and sometimes in *February*, the fruite is ripe in *August*. The last flowreth not untill *May*, and the fruite ripeneth not untill *September* be well over.

*The Names.*

The first is called in Greeke κρανεία in Latine *Cornus* and *mas*, to distinguish it from the other, which is called by *Theophrastus* θηλυκρανεία *Cornus fœmina*. There is much doubt and question among many of our later Writers, about this female Cornell (for of the male there is no doubt, all calling it *Cornus mas*, or *sativa*,) whether it should be the *Virga Sanguinea* of *Pliny*, or the *Hartriegell* of *Tragus*, or his *Faulbaum*, some referring it to the one, some to the other, but the generall tenet of the most is, that in most things it answereth both to the *Thelycrania* of *Theophrastus*, and may well enough agree with the *Virga sanguinea* of *Pliny*: *Cordus* calleth it *Pseudocrania quasi falsa Cornus*, and *Dodonæus*, besides that he calleth it *Cornus fœmina*, taketh it to be the *Opulus Columellæ*. *Bellonius* saith in the 56. Chapter of his first Booke of Observations, that he found that shrub, which the *French* in imitation of the Latines call *des Sanguins*, and the auncient Grecke *Cornus fœmina*, betweene *Philoppos*, and *Bucephala* to be little inferiour unto our greatest male Cornellian trees, thereby esteeming them to be both one: The *Italians* as *Matthiolus* saith, call it *Sanguineo*, and *Sanguinello*, but whether it be *Tragus Hartriegel*, we are not well assured, for he saith that the wood thereof is so hard that it can very hardly be bored, and therefore serveth for many Country instruments, and long lasting for the hardnesse, which we can not say so of this; we for the most part call it the Dogge berry tree, because the berries are not fit to be eaten, or to be given to a dogge. I heare they call this in the North parts of the Land, the Gatter tree, and the berries Gatter berries, yet some say they call the *Enomymus* so.

*The Vertues.*

The male Cornell is a fruite very good and wholesome, pleasant with the austerity, and helping to binde the belly subject or molested with a laske: both leaves and buds saith *Galen*, doe dry exceedingly, and therefore are good to soder up great wounds in strong bodies, but not so fit in small cuts, and more tender persons, because it dryeth too much in such cases: The Conserve made of the fruite, is of especiall use in all fluxes both in man and woman, the liquour that commeth out of the leaves or stalkes, being heated with an iron, that the iron touch them not, is good to heale tetters, and ringwormes. The Female Cornell or Dogge berry, is put to no use that I know, yet *Matthiolus* saith that the people in *Italy*, by boyling the berries, make an oyle that serveth for their Lampes. If one that is cured of the biting of a madde dogge, shall within one twelve moneth after touch the *Cornus fœmina*, or Dogge berry tree, or any part thereof, the disease will returne againe. *Sckimkins observation.*

## CHAP. LXXXV.

### *Lotus.* The Lote or Nettle tree.

ALthough divers Authours have publiſhed ſundry trees, under the name of *Lotus*, as *Injuba*, *Laurocerasus*, and many others, yet there is knowne unto us but one true kinde, that is called *Lotus*, the Lote or Nettle tree, yet I thinke not amiſſe to joyne two or three other plants, which may not unfitly be referred to it.

1. *Lotus ſive Celtis arbor.* The Lotē or Nettle trēe.

The true Lote or Nettle tree groweth to a great heighth, whoſe body and elder branches are covered with a ſmooth darke greene barke, the younger being more greene, whereon grow ſomewhat rough or hard leaves, long pointed, and ſomewhat deepely dented about the edges, like unto a Nettle leafe, of a darke greene colour, and often grow yellow toward Autumne: the flowers ſtand here and there ſcattered on the branches, after which come round berries like unto Cherries, hanging downewards upon long footeſtalkes greene at the firſt, whitiſh afterwards, and reddiſh when they are full ripe, but blackiſh if they be ſuffered to hang too long on the branches, of a pleaſant auſtere taſte, with an hard round ſtone within them. There is ſaid by *Theophraſtus*, if this be his firſt *Lotus*, to be another ſort without ſtones, whereof Wine was made, that would not laſt above two or three dayes.

*Vine offi-cula.*

2. *Arbor Guajacana ſive Guajacum Patavinum.* The Indian Date Plumme tree.

The Indian Lote tree groweth great, with a ſmooth darke greene barke, ſhooting forth many large boughes, and ſlender green branches, beſet with faire and ſomewhat broad green leaves, ſomewhat like unto the leaves of the Cornell tree, but larger, without any dents on the edges, the flowers grow along on the branches, cloſe ſet unto them, without any or with a very ſhort footeſtalke under them; conſiſting of foure greene leaves, as the huske, and foure other within, of a darke purpliſh red colour, the fruite that followeth ſtandeth in the middle of the ſaid huske, cloſing it round at the bottome, and is greene at the firſt, and very harſh, but red and round when it is ripe, and ſomewhat like a Plumme, with a ſmall point at the head, and then of a reaſonable pleaſant taſte or relliſh, wherein in the hotter climates, but ſeldome in ours or not with me, are contained thicke and flat browne griſtely ſeedes or kernels, ſomewhat like unto the kernells of *Caſſia Fiſtula*, which may be ſomewhat eaſily cut with a knife.

3. *Guajacum Patavinum anguſtifolium.* The Indian Date Plumme trēe with narrow leaves.

This differeth little from the laſt, either in ſtemme or fruite, but onely in the leafe, which is longer and largēr then it.

*Lotus arbor.*
The Nettle tree.

2. *Guajacum Patavinum.*
The Indian Date Plumme tree.

4. *Piſtacia*

3. *Guajacum Patavinum angustoribus foliis.*
The Indian Date Plumme tree with narrower leaves.

4. *Pishamin Virginianum.*
The Virginian Date Plumme or Pishamin.

4. *Pishamin Virginianum.* The *Virginia* Date Plumme or *Pishamin.*

This other kinde, which differeth but little from the second (if it be not all one with it, or at least a greater sort, whereof I am more then halfe perswaded, they doe so neere agree together) hath growne also with me, raised from the kernell were sent with the fruite out of *Virginia*, and grew in a short time to be of seven or eight foote high (which upon remooving perished) but there groweth to be a great tree, whose wood is hard and brittle, and somewhat whitish, but covered with a thin darke green barke: the branches are many and slender, with a thinner grayish barke on them, whereon are set many faire broad greene leaves, without any dent on the edges, and very like unto the former. It hath not borne flowers or fruite in our Country that I can heare of as yet with any, but the fruite as it came to us, was in forme and bignesse like a Date, covered with a blackish skinne set in a huske of foure hard leaves very firme like a Date, and almost as sweete, with three or foure great flat thicke kernels within them, very like unto the former, but larger by the halfe.

*The Place* and *Time.*

The first groweth in *Italy* in divers places, naturall as it is said: but in many especiall places there, and in *Provence* of *France*, and *Mompelier*, growne great trees, and so also in some places with us: The second came to me from *Italy*, by Master Doctour *Iohn More*: and groweth now in my Garden, but came as it is said out of the West Indies, for *Dalechampius* had it from *Florence*, where they called it *Uva d'India*, and planted it about *Lyons* in *France*: The last as I said came from *Virginia*: The first flowreth earlie, and ripeneth the fruite also sooner then the last.

*The Names.*

The Lote tree is called in Greeke λωτὸς δένδρον, and so in Latine *Lotus arbor*, to distinguish it from all the other kindes of *Lotus herba*, which are very many. The first is the *Lotus* of *Dioscorides*, which *Pliny* calleth *Lotus Celtis*, and supposed to be the first *Lotus* of *Theophrastus*, which grew in an Island called *Lotophagia Insula*, or *Pharis*, but now called *Garbi*: as also in *Africa*, where as *Theophrastus* saith, the army of *Ophellus* passing to *Carthage*, were fed with the fruite of this tree for many dayes, they or the people where they grew most abundantly, being called *Lotophagi*, Lote eaters, whereof *Homer* also *lib. 9. Odyss.* speaketh that *Ulysses* followers so liked the sweete fruite that they could not be driven from them without blowes, to their shippes againe, (yet some referre this narration to the *Zizipha*) And is generally called *Lotus Celtis* or *arbor*, by all Writers, which *Guilandinus* saith the *Italians* call *Bagolaro*; and *Anguilara Arbor del perlaro*, and *Perlaro*. The *French Micocoulier*, and *Cacavia* by the *Candiots*, as *Bellonius* saith. *Theophrastus* and *Pliny* make mention of another sort of this *Lotus*, without stones, whereof was made a kinde of Wine, that would not endure above two or three dayes, which fruite is as yet unknowne in these dayes. The second is called *Guajacum Patavinum Fallopio* by *Gesner in hortis*, and *Lobel*, who also taketh it to be the *Lotus vera Theophrasti*, who are both in an errour, *Fallopius* that tooke it for

*Guajacum*, and *Lobel* that taketh it for *Lotus vera*. *Matthiolus* calleth it *Pseudolotus*, and saith that it came from *Angerius de Busbecke*, who sent it from *Constantinople* by the name of *Dactyli ex Trapesonda dulces*, but assuredly either *Busbecke* or *Matthiolus* were deceived therein, a contrary fruit being given them under that name, for the name agreeth not with his description, which is indeed the description of this *Guajacum*, for by that name of *Trabison Curmasi Dactylus ex Trapezunte*, hath the *Laurocerasus* beene sent from *Constantinople*, as both *Camerarius* and *Clusius* doe set it downe, which is much differing from this. *Camararius* and *Bellonius* calleth it *Guajacana*, *Cæsalpinus Ermellinus*, who also taketh it to be the *Tuberum alterum genus Pliny*. *Lugdunensis* as I said before, taketh it to be the *Diospyros* of *Theophrastus*, *lib.3.c.13.* and the *Faba Græca* of *Pliny*. *Matthiolus* calleth the third *Lotus Africana altera*, or *Loti Africanæ species*. The last hath the name in the title, as it came to us, and for the likenesse I doe set it with them, if as I said it be not the very same: and is also likely to be the *Loti Africanæ altera species*, as the figure thereof plainely sheweth.

*The Vertues.*

The berries of the Nettle tree doe binde the belly, and the shavings of the wood made into a pouther and drunke, or boyled in Wine or water and drunke, helpeth women that are troubled with the abundance of their courses, and the laskes of the belly also: the same decoction maketh the haire to become yellow, and stayeth the falling of them. The fruite of the other while they are greene and unripe are so harsh as they are able to draw their mouthes awry that shall eate them, but when they are full ripe are reasonable sweet and pleasant: but what other property they have, I have not yet understood.

## CHAP. LXXXVII.

### *Lentiscus.* The Masticke or Lentiske tree.

THe *Arbores resiniferæ*, come next to be entreated of, that is, those trees that beare Rossin-like Gummes, which are divided into two sorts, that is, into those that beare berries, and those that beare Cones. The berry bearing trees are these *Oxycedrus*, the prickely Cedar, *Cedrus Lycia*, the Cypresse like Cedar, the greater and the lesser, *Sabina utraque*, both sorts of Sabine. *Iuniperas major*, the greater Iuniper tree, of all which I have before in this worke spoken, some adde *Taxus* the Yew tree, but I see no reason for it. There remaine some others to be intreated of, and the Masticke tree first, whereunto I thinke meete to joyne two other strange trees of the West Indies, which are referred hereunto for their likenesse; the rest of them which are the Turpintine tree, the Balsame tree, the Storax tree, and the Dragon tree shall follow each in their order.

1. *Lentiscus.* The Masticke tree.

The Masticke tree groweth like a tree, if it be suffered to grow up, and often also riseth but as a shrubbe, whose body and branches are in colour alike, that is of a reddish colour, tough and gentle: and doe somewhat bend downe their ends, whereon grow winged darke greene leaves consisting of foure couple, each of the bignesse of the large Myrtle leafe, standing one against another, without any odde one at the end, with a reddish circle about their edges, and some reddish veines on the underside also, smelling sweete and abiding greene alwayes on the bushes, the flowers grow in clusters at the joynts with the leaves, being small, and of a pale purplish greene colour, and after in their places stand small blackish berryes, of the bignesse of Pepper cornes, with a hard blacke shell under the outer skin, and a white kernell within, it beareth besides these berries certaine hornes, with a certaine cleare liquour in them, which turneth into small flyes, that flye away: it giveth also a cleare white gumme in small droppes, when the stockes are wounded in sundry places, which is gathered with great care and attendance.

2. *Lentiscus Pervana.* The Indian Masticke tree.

This Indian Masticke groweth as high as any high Masticke tree, spreading long and pliant branches, bending downewards, covered with a tough reddish barke, set with long winged leaves, made of many leaves, set by couples, with an odde one at the ends, of a sad greene colour, and a white ribbe in the middle, with rugged veines transversing them, conspicuous chiefely underneath, being plaine and not dented about the edges, and being bruised have no evill sent: the flowers come forth in sparsed tufts together on a stalke, an handbredth long, consisting of five small white pointed leaves a peece, after which succeed small round berries, like those of the former Masticke tree, upon short footestalkes, of the bignesse of Pepper cornes, greene at the first, red after, and blacke being ripe, and as sharpe and hot in taste as Pepper, somewhat oylie, covered with a thin skinne, and the inward kernell of a very sharpe sent and taste. We have had a cleare white gumme in great lumpes or peeces brought us from some of our *English* plantations in the West Indies, which they called Masticke, and in the chewing was tenacious like Masticke, whether the tree from whence it was taken was answerable to this or the next, we are not certaine, because there was no relation sent thereof unto us with it.

3. *Lentisci Peruani similis Molle dicta.* The Indians Molle.

*Clusius* maketh mention of a tree called Molle, received from the West Indies, which as he saith might be the same with the former and differing but in age, but because there seemeth manifest difference betweene them, I thought good to sever them, and shew you it with this description that he hath given it. There rose saith he, two small plants, with the worthy Signiour *Iohn Brancion*, at *Mechlin*, from seedes that were called Molle by the West Indians, but perished by the extremity of the Winter, the third yeare after they sprang up: but the stems of them being young, were of a darke greene colour, with divers small ash-coloured spots thereon, the leaves were winged like those of the Ash, but much smaller, of a darke greene colour, dented about the edges, and the end leafe longest, yeelding a white, thicke, and glutinous sweete milke when they are broken, and being bruised smell like Fennell, having an astringent taste: it gave no flowers, but *Lobel* sheweth the flowers were yellow, but the berries that were sowne and sprung, were as bigge almost as Pepper cornes, covered with a reddish skin, and clustering together like unto a small cluster of Grapes: the gumme hereof is said to be sweete in smell.

The

1. *Lentiscus.* The Masticke tree.

2,3. *Lentiscus Peruana & Molle Clusij serratis foliis.* The Indian Masticke tree, and the Indian Molle somewhat like it.

*The Place* and *Time.*

The first groweth as well in *Provence* of *France* as in divers places of *Italy*, and in *Candy* also, and in many places of *Græcia*, but yeeldeth little gumme there, but especially in the Isle of *Chio*, now called *Sio*; they tend, pruine, and manure it with as great paines and care, as others doe their Vines, which goeth beyond them in the profit of the gumme: It flowreth in *Aprill*, and the berryes ripen in *September*, and not at severall times, as these Verses of *Aratus* would intimate.

*Jam vero semper viridis semperque gravata*
*Lentiscus, triplici solita est grandescere fætu.*
*Ter fruges fundens, tria tempora monstrat arandi.*

As it is there set downe. The second was brought from *America*, and grew, as *Bauhinus* relateth it, in Cardinall *Columna* his Garden at *Rome*, where it grew great, which also as it is likely was the same that *Clusius* saith *Everardus Verstius* saw there, and as he saith likewise Doctor *Tovar* of *Sivil* in *Spaine*, sent him such like branches with the unripe fruite in clusters to see, but as he saith, called Molle by *Tovar*; *Lobel* also exhibiteth a branch hereof with the next that is dented, at the beginning of his tractate *de Balsamo*: *Clusius* himselfe also having gained a branch hereof from some place not specifyed, setteth it downe as taken from a tree growne old. The last is mentioned likewise by *Clusius* in his Annotations upon *Monardus*, to grow as all the Chronicles, or Writers of the West Indians say, in all the Vallies and Champion grounds of *Peru*, and especially *Cieza*. *Petrus de Osma* also in his Letter to *Monardus* saith it grew at *Lima* in *Peru*.

*The Names,*

The Masticke tree is called in Greeke σχῖνος (not σχοῖνος which is *Iuncus odoratus*) *quasi* σχιστὸς *fissilis quod facile & frequenter in dentiscalpia findatur*, and the berries σχίδαι and not σχοῖδαι, as some coppies have it, in Latine *Lentiscus a foliorum lentore fortasse* by which name all Authours call it, and the gumme *Resina Lentiscina*, and *Mastiche*, and *Mastix* by some, by the *Arabians Gluten Romanum*; *Dioscorides* maketh mention of a greene gumme as well as a white, and *Galen* of a blacke sort that was of *Egypt*, both which are not knowne in these dayes: in *Candy* and some other places, their trees yeeld a yellowish bitter Masticke, but no where so good, and so plentifull in all the world, as in the Isle of *Sio* in the *Egeon* Sea: there is another sort of Masticke which is called *Acanthice*, or *Spinalis* as *Gaza* translateth it, because it is gathered from a prickly thistle, as I have shewed among the Thistles, in the Chapter of *Chamæleon* and *Carlina*. In former times our Apothecaries shops were furnished with no other *Xylobalsamum*, then the sprigs of *Lentiscus*, I would the errour might not be continued: The second is called Molle by *Tovar*, as I said before, and by *Clusius* in his *Curæ posteriores*; but by *Bauhinus Lentiscus Peruana*, and following *Clusius* saith, that it beareth the leaves according to the growth, being dented while it is young, and without dents growing older, which how dissonant me thincks this is to reason, in this plant let others judge upon my judgement, & the forme of the growing the one from the other, for the one that is dented

dented hath an end leafe, bigger and longer then all the reſt, which ſheweth I am perſwaded a manifeſt difference in *ſpecie*, from this that is not dented, for I cannot be perſwaded that any plant, ſhould ſo much differ in forme from it ſelfe in the time of age and youth. The laſt is alſo as I ſhewed called Molle by the Indian Writers, whoſe ſent is like Fennell, when as the other is not ſo, and is for the likeneſſe referred to the *Lentiſcus Pervana* by *Baubinus* in his *Matthiolus, &c.* following *Cluſius* therein, to be both one, & by *Lobel* joyned with the former and the *Balſamum verum*, making it to agree with the properties therof in many things, *Baptiſta Ferrarius* alſo in his *Flora* mentioneth it by the name of *Tereanithus anguſtifolia* pag. 372. citing the third Book, and 15. Chapter of that great Book of the Weſt Indian plants, beaſts, &c. begun to be Printed more then twenty yeares ago at *Rome*, whoſe title is *Thesaurus rerum medicarum novæ Hiſpanæ, &c.* The *Arabians* call the Lentiske tree *Darn*, the *Italians Lentiſco*, the *Spaniards Mata* and *Arveria*, the *French Lentiſque*, and thoſe of *Narbone Reſtiucle*, the *Germanes Maſtichaum*, the *Dutch Maſtickboom*, and we in *Engliſh* the Lentiske or Maſticke tree.

*The Vertues.*

The Lentiske tree is binding in the ſecond degree, or in the beginning of the third, and temperately hot: all the parts thereof are binding, that is, both roote and branch, both barke and leafe, both fruite and gumme, and doe binde and ſtop all fluxes, and ſpittings or caſtings of blood, and is good to ſtrengthen a weake ſtomacke, and helpe the falling downe of the mother or fundament: the decoction fomented, healeth up hollow ſores, and ſodereth broken bones, faſteneth looſe teeth, and ſtayeth creeping ſores, and doth as much as *Acacia* or *Hypociſtis*, and even the juyce of the leaves is as good a ſubſtitute for *Acacia* as any other: the oyle that is preſſed out of the berries, helpeth the itch, the leproſie and ſcabbes, both in men and beaſts: the gumme Maſticke doth binde and ſtay fluxes in like manner taken any way in pouther; or if three or foure graines be ſwallowed whole at night when you goe to bed, it not onely eaſeth all paines in the ſtomacke, but keepeth it from the like afterwards, the pouther of Maſticke with Amber and Turpinte is good againſt the running of the reines, and for both whites and reds in women: the pouther thereof mixed with Conſerve of red Roſes, helpeth to ſtay the deſtillations of thinne rheume on the lungs, cauſing a continuall cough and ſpitting of blood, and if ſome white Francumſenſe in pouther be mixed with it alſo, it worketh the more effectually, the ſame alſo comforteth the braine, procureth an appetite to meate in moiſt fluxible ſtomackes, ſtayeth caſtings, and maketh a ſweete breath: the ſame being heated in Wine, and the mouth, gummes, and teeth waſhed therewith, cleanſeth and faſteneth the corruption, and looſeneſſe both of gummes and teeth: it is alſo much uſed in ſalves and plaiſters, to mundifie and heale ulcers, and ſores, to ſtay the fretting fluxes of humours to them, to dry them up, and to fill up the hollowneſſe: it ſtrengthneth and bindeth alſo the parts, whereunto it is applyed, and comforteth the aking joynts and ſinews wonderfully. The oyle that is made of Maſticke by infuſion and ebullition, *ſecundum artem Pharmaceuticam*, is ſingular good in all the aforeſaid diſeaſes, moderately comforting, mollifying and binding, and is effectuall againſt all the aforeſaid diſeaſes of the mother, againſt all paines in the belly, colon the chollick, and the ſtomacke, the hardneſſe of tumours, and the paines of the joynts and ſinewes, it likewiſe comforteth the braine, and ſtrengtheneth both the liver and heart, but one droppe of the pure Chymicall oyle drawne from Maſticke is more effectuall then one ounce of the former oyle, for it deſerveth more commendations then is given it. The effects of the Indian Molle is recorded by thoſe have written of it firſt, that of the berries, they make a wholeſome kinde of Wine or drinke being boyled with water, and according to the boyling of them either vinegar or honey: the decoction of the leaves is good to helpe cold griefes, and applyed warme to woundes after cloathes be dipped therein helpeth their cure more ſpeedily, the pouther of the barke alſo of the tree, ſtrewed or caſt into them doth cleanſe, ingender fleſh, and heale them quickely and perfectly: with the decoction alſo of the barke, the ſwellings and paines of legges and thighs, are much comforted and helped; the ſaid pouther of the barke doth helpe to faſten looſe teeth, and looſe gummes, aud of the wood is made fine and good toothpickes: the gumme diſſolved in milke and dropped into nhe eyes taketh away the dimneſſe or miſtineſſe of them.

---

## CHAP. LXXXVIII.

*Tere binthus.* The true Turpine tree.

ALthough *Bauhinus* in his *Pinax* doth make three ſorts of Turpintine trees, taking his ground from *Rauwolfius* who maketh two ſorts beſides the ordinary one, yet I am of *Cluſius* his opinion that the greater ſort is the *Terebinthus Indica* of *Theophraſtus*, which is the Piſtake tree mentioned before, ſo that the other two ſorts we hold well to be differing Turpintines with other good Authours, and to be here deſcribed unto you: yet we doe not intend to diſtinguiſh them by *mas* and *fœmina*, as *Theophraſtus* doth, that the male is barren, and the female fruitefull, the one bearing red berryes which come not to ripeneſſe, and the other greene at the firſt, red afterwards, and blacke, and of the bigneſſe of a Beane when they are ripe: but *Cluſius* ſaith, that enquiring diligently thereafter, he could heare of no ſuch differences, unleſſe it may be ſaid to be a difference when ſome fruite trees bring their fruite to ripeneſſe, when others are empty or idle, by ſome caſualty or ill ſtanding: but by the leaves, the one bearing broader and the other narrower leaves.

1. *Terebinthus latifolia.* The broader leafed Turpintine tree.

This Turpintine tree in many places groweth but like a ſhrubbe, yet in ſome to be a great treë, the barke of whoſe body and greater branches are of an aſh colour, the leſſer being greeniſh, and red while they are young, ſparingly ſet with large winged leaves like unto the Piſtacke tree but larger, every leafe being as great as a Bay leafe, and pointed, not round which putteth the difference betweene them, and ſmelling ſomewhat like a Bay, falling away, and not holding on in Winter: the flowers are moſſie like the Ollive bloſſomes, and grow on long ſtalkes comming out of certaine knots, from the ends of the branches, a number of them in ſmall tufts ſet in a cluſter together, of a purpliſh browne colour, which paſſe into ſmall berryes, ſomewhat bigger and longer then thoſe of the Maſticke tree, and very like unto the true *Carpobalſamum*, greene at the firſt, reddiſh after, and of a blewiſh colour, tending to greene when they are ripe, glutinous in handling and ſticking to their fingers that touch them, having a kernell within them: moſt of thoſe berries that grow red before they be ripe, fall away being

empty

empty and idle: this beareth also certaine red hollow skinny bladders, like long hornes, full of a clammy blackish liquour, which breed small flyes or gnats in them: This being wounded in sundry places yeeldeth forth a liquid Rossen or cleere Turpentine, but nothing so thinne as that of the Larch tree.

2. *Terebinthus angustiore folio vulgatiore.*

The narrow leafed Turpintine tree.

This tree is in all things like the former, but that it never riseth so high, and the leaves are long and narrow, much smaller then the former, the berryes are many of them red on the stalkes at their full time, which declareth them to be empty huskes, and no good seed, and but some that will be full and good.

*The Place* and *Time.*

The Turpintine tree groweth in *Narbone*, and *Provence* in *France*, in sundry places of *Italy*, and *Spaine*, *Cyprus* and *Greece*, where for the most part it abideth small, and low, but groweth very great and high in *Syria*, *Arabia*, *Cilicia*, *Armenia*, and other those *Levant* Countries, as *Bellonius* hath observed: the second as *Lobel* saith, is much the more frequent in all the places about *Provence*: They flower somewhat earely in the Spring, and the fruite is ripe in *September* and *October*.

*The Names.*

It is called in Greeke τερμινθος, and in Latine *Terebinthus*, and the Turpintine ῥητίνη τερμινθινη, *resina terebinthina*, the true Turpintine tree was not knowne in divers of these later ages before ours, for as *Matthiolus* saith, the liquid Rossen of the Larch tree had by time obtained the name of Turpintine, and so was used, no man thinking that there was any truer to be had, untill the search of diligent men, had brought the true Turpintine to light againe, that so long time had lyen hid from our Predecessors. The first is the *Terebinthus* of *Matthiolus*, *Lugdunensis*, and others, and the *Terebinthus Lentisci folio* of *Lobel*. The other is the *Pistachiæ folio* of *Lobel*, and the *Terebinthus major* of others. The *Arabians* call it *Botin* and *Albotin*, the *Italians Terebinto*, the *Spaniards Cornicabra*, the *French Tereminthe*, the *Dutch Termentijn boom*, and we in *English* the Turpintine tree.

*The Vertues*

The leaves, the barke, and the fruite of the Turpintine tree are hot and dry in the second degree, and doe binde, strengthen, and repell, but the Turpintine doth heate, clense, and purge, draweth, and mollefyeth and excelleth all other Rossens, yet *Galen* for some causes preferreth Masticke, that is, in binding and strengthening; the berryes being dry are very neere unto the third degree of dryness so that they provoke urine, and are good for the spleene, and for the biting of the Spider *Phalangium*: of the berryes is made an oyle, as out of the berryes of the Lentiske tree, which heateth and bindeth, and is good in crampes, convulsions, hardnesse of the sinewes, and to close wounds: the berryes themselves are much eaten by the people in *Turkie* where they grow and make them their daily food, warming, comforting, and opening the uritory passages, and withall provoke lust: the Turpintine heateth, mollefyeth, resolveth, digesteth and clenseth: if a dramme or two be taken in a reare egge it wonderfully helpeth the cough, which commeth by flegme, stopping the lungs, wheesings, and shortnesse of breath, and all imperfections of the chest by flegme: it clenseth the backe and reines, and stayeth the gonorrhæa, with a little dryed Rubarbe in pouther put thereto: it provoketh urine, and helpeth to breake and expell the stone and gravell, it ripeneth Impostumes and helpeth to expell them, and mightily dissolveth winde in the paines of the chollicke, of the stomacke or sides, and is good also against the gout, Sciatica, and all paines in the joynts, as well to take it inwardly with some *Chamæpitis*, Sage, and *Stæchas*, as to be made into a searcloath and applyed thereto: it is a speciall ingredient into those Balsomes that are to heale any greene wounds, and is singular effectuall in all wounds, and fractures in the head, all punctures in the flesh or sinewes, and all breakings out in the skinne, be it itch or scab, be they piles, pushes or wheales: it draweth forth splinters, thornes or the like out of the flesh, and healeth the chaps of the lips, hands, fundament or other parts: briefely it is put into all salves, oyles, oyntments, or plaisters, that serve to clense ulcers, to draw and heale any sores, or to warme and comfort any cold or weake parts: these things the true Turpintine performeth better then any other, which from hence hath drawne both the name and use: the Chymicall oyle of this Turpintine is wondrous effectuall in many of these diseases, if it be carefully applyed, for it is by farre of more subtill parts, being the purer and more subtill spirits, whereby they heate and penetrate much more, and therefore inwardly or outwardly must be used in lesser quantity, and as it were but by drops. There are in the Easterne Countries of *Turkie*, as *Bellonius* recordeth, much use made of the young hornes of the Turpintine tree, before they are growne great, for he saith many thousand pounds weight of them are gathered while they are no bigger then Gaulles, to serve the Dyers there to dye their silke, which shall hold the colour fresher and firmer then any that is Dyed without them.

*Terebinthus cum flore & corniculo.*

The Turpintine tree flowring and with the horne thereof.

CHAP.

## CHAP. LXXXIX.

*Balſamum genuinum antiquorum.* The true Balme or Balſame tree of the ancients.

TO deliver unto you this Balſame tree as I ſhould, and as it ought and deſerveth, I ſomewhat doubt of my ability, for who is fit for ſo rare, ſo excellent a ſubject, being heretofore accounted as one of the greateſt jewels, and richeſt endowments of the earth, and as a parcell of the treaſure of great Kings, and Princes, and it is thought by many that the greateſt and worthyeſt preſent that the Queene of *Sheba* did or could bring and give unto King *Salomon*, was ſome Balſame trees, which ſhe brought out of her Country, that *Salomon* might plant them in his: and it was alſo one of the greateſt Iewels the firſt *Ptolomoy* could bring away from thence into *Egypt*, as Authours doe record it: but now the times are ſo changed, that I thinke I ſhall ſcarce gaine credit, that the ſame true *Balſamum* is extant in *rerum naturâ*: but leaſt my gates grow greater then my City, and ſo it runne out at them, let me leave any further preamble, and ſhew you the thing. The Balſame or Balme tree, never groweth very great, no not in the naturall places, being ſuffered to grow as it will, but unto five or ſixe cubits high or thereabouts, and in others much lower, with divers ſmal and ſtraight ſlender branches iſſuing from thence, of a brownish red colour, eſpecially the younger twigs, covered with a double barke, the red outermoſt, and a greene one under it, which are of a very fragrant ſmell, and of an aromaticall quicke taſte, ſomewhat aſtringent and gummy, cleaving to the fingers, the wood under the barke being white, and as inſipide as any other wood; on theſe branches come forth ſparſedly and without order ſundry ſtalkes of winged leaves, ſomewhat like unto thoſe of the Maſticke tree, conſiſting ſome but of three leaves which are thoſe that firſt come forth and the loweſt, others of five or ſeven leaves, and ſeldome above, which are ſet by couples, the loweſt ſmalleſt, and the next larger, and the end one largeſt of all, of a pale greene colour, ſmelling and taſting ſomewhat like the barke of the branches; a little clammy alſo, and abiding on the buſhes Winter as well as Summer: The flowers are many and ſmall, ſtanding by three together on ſmall ſtalkes, at the ends of the branches made of ſix ſmall white leaves a peece, which are ſucceeded by ſmall brownish hard berries, little bigger then Iuniper berryes, ſmall at both ends, creſted on the ſides and very like unto the berryes of the Turpintine tree, of a very ſharpe ſent, having a yellow hony like ſubſtance within them ſomewhat bitter, but aromaticall in taſte, and biting on the tongue like the *Opobalſamum*: From the body hereof being wounded, commeth forth a liquour (and ſometimes a little of it ſelfe without ſcarifying) of a troubled whitiſh colour at the firſt, which after ſome ſmall time groweth cleare, being ſomewhat thicker then oyle in Summer, of ſo ſharpe a piercing ſent, that it will pierce the noſtrils of them that ſmell thereunto, like unto oyle of ſpike almoſt, but as it groweth in age, ſo it decayeth both in the thinneſſe of the ſubſtance growing thicker, and in the ſmell nothing ſo quicke, and in the colour becomming yellow like hony, or browne thicke Turpintine, as it groweth older.

*Balſamum genuinum antiquorum.*
The true Balme or *Balſamum* tree of the ancients.

### *The Place* and *Time.*

*Arabia fœlix* about *Mecha*, and *Medina*, and a ſmall village neere them called *Bedrunia*, with the hils, valliés, and ſandy grounds about them. and the Country of the *Sabæans* next it, are thought by many to be the onely naturall places, where this tree hath beene ever knowne in theſe or the former dayes to grow, and from thence hath *Iudæa* and *Egypt* ever beene furniſhed, whatſoever hath growne therein as *Alpinus* relateth; but it is ſomewhat probable to me, that the hils of *Gilead* did nouriſh this tree long before the Queene of *Shæba* brought any as it is thought to *Salomon*, in that the *Iſhmalites* that bought *Ioſeph* of his Brethren, as it is ſet downe *Gen.* 37. *v.* 24. are ſaid to carry from *Gilead*, Balme &c. downe to *Egipt*, and *Gen.* 43. 11. *Iacob* willeth his Sonnes to carry to *Ioſeph* in *Egipt*, ſome of the beſt fruites of the Land, *ſc.* Roſſin &c. which I take to be underſtood this Balme, or elſe Roſſin ſimply might be thought too ſimple a preſent for *Ioſeph*, and not one of the beſt fruites of the Country: but I doubt of the truth of that tale that the Queene of *Shæba* did firſt bring the Balſame trees to *Salomon*, and that he planted them in the valley by *Iericho*, but rather that they were fetched from the hils of *Gilead*, and planted by him there in Orchards, the better to be tended. *Ieremy* the Prophet doth alſo often mention the Balme of *Gilead*. And yearely pruined both by the *Iewes* and *Arabians*, to have the greater ſtore of liquor. It flowreth in the Spring with the Turpintine tree, and fructifyeth with it in the Autumne.

### *The Names.*

From the *Arabians* who call it *Baleſſan*, have the Greekes called it βαλσάμον, and the Latines *Balſamum*: the liquour

liquour they call ὀποβάλσαμον *Opobalſamum*, or βαλσαμέλαιον *Balſameleon*, and the berryes or fruite of the tree καρποβάλσαμον *Carpobalſamum*, and κασσαμον *Caſſamum*, and the ſprigs or young branches thereof ξυλοβάλσαμον *Xylobalſamum*. Divers of the auncient Writers have made mention of this tree, but ſo diverſly that many do thinke they wrote of a thing that was not, or that was not ſeene and knowne unto them, at the leaſt the deſcriptions are ſo lame and ſeeme ſo to vary one from another, yet if they be warily and wiſely conſidered, they may be brought in ſome ſort to agree thereunto, but for me to argue much in this matter, and the particulars would require a great deale of time and roome, which cannot be ſpared here, I muſt referre them to *Alpinus* and *Belloni-us*, that would be further ſatisfied herein, who have more largely entreated of this ſubject.

*The Vertues.*

This Balſame tree ſaith *Galen*, is hot and dry in the ſecond degree, ſo that it is ſweete in ſmell being of thinne parts: but the liquor or *Opobalſamum*, is of more thinne parts then the plant it ſelfe: the fruite or berryes is very like it in quality, but farre inferiour thereunto in the ſubtility: The liquour or *Opobalſamum*, is of great good uſe againſt all poyſons and infections, both Vipers, Serpents and Scorpions, the peſtilence and ſpotted fevers, and all other putride and intermiſſive agues that riſe from obſtructions, and crude cold humours, to take a ſcruple or two in ſome drinke for ſome dayes together, and to ſweate thereon, for this openeth the obſtructions of the liver and ſpleene, and digeſteth thoſe raw humours in them, cheriſhing the vitall ſpirits, radicall moiſture, and naturall heate in them and is very effectuall in all cold griefes and diſeaſes of the head or ſtomacke, helping the ſwimmings and turnings of the braine, weake memories, and the falling ſickneſſe: it cleareth the eyes of filmes or skinnes, overgrowing the ſight, and eaſeth the paine in the eares, and their deafeneſſe and other diſeaſes, to be dropped into the eyes or eares, it helpeth the cough, ſhortneſſe of breath, and conſumption of the lungs, by warming and drying up the diſtillations of rheume upon them, and all other diſeaſes of the ſtomacke proceeding of cold or winde, the cold or windy diſtempers alſo of the bowells, wombe or mother, procuring torments and paines, or the cold moiſtures procuring barrenneſſe, procureth the courſes, delivereth the dead birth and after birth: the fluxe alſo of the whites and the ſtopping of urine: it cleanſeth alſo the reines and kidneyes, and freeth them from the generation of ſtones in them, and expelleth the gravell or ſtones in them: it is ſingular good againſt the palſie, crampe, tremblings, convulſions or ſhrinking of ſinewes, and for greene wounds, the moſt ſpeedy operatour of any: from the ſingular effect whereof all other medicines made for the health of the body or to heale wounds were called *Balſamum*, Balme. The women in *Egypt*, herewith as *Alpinus* ſheweth, preſerve their beauty, and young forme for a long time, the berryes are eſpeciall good againſt poyſons and infections, the falling ſickneſſe, the ſwimmings and paines in the head, the cough, and diſeaſes of the lungs, the windy paines and ſtiches in the ſides, the reſtraint of urine, and the riſing of the mother and other diſeaſes thereof to ſit in a bathe made of them: the wood worketh the ſame effects but in a farre weaker manner.

## CHAP. XC.

### *Styrax arbor.* The ſweete Storax tree.

BEſides the Storax tree, that hath uſually been knowne and deſcribed by allmoſt all Writers of Herbs, and which I am now about to ſhew you, *Bauhinus* from *Honorius Bellus* in *Candy*, hath exhibited another ſort, whereof he is ſo brieſe, that little more can be aſſured thereof by his relation, then the name, and the confidence of his judgement from whom he had it, that it may be referred hereunto. A third ſort is the *Storax rubra*. whereof we have leſſe knowledge then of the laſt.

1. *Styrax arbor vulgaris.* The uſuall Storax tree.

This Storax tree groweth very like unto the Quince tree, both for forme and bigneſſe, the leaves alſo are long and round, and ſomewhat like but farre leſſe, whitiſh underneath and ſtiffe. The flowers ſtand both at the joynts with the leaves, and at the ends of the branches, conſiſting of five or ſixe large whitiſh leaves, like unto thoſe of the Orrenge tree, with ſome threds in the middle, after which come round berries, ſet in the cups that the flowers ſtood in before, of the bigneſſe of Haſell nuts, pointed at the ends, and hoary all over, each ſtanding on a long footeſtalke, containing within them certaine kernels in ſmall ſhells: this yeeldeth a moſt fragrant ſweete gum, and cleare, of the colour of browne hony, if we might have it ſincere without mixture, which yet wee in ſmall drops have had.

2. *Styrax folio Aceris.* A Storax with Maple leaves.

From a round blackiſh rugged roote covered with a creſted, or as it were joynted barke come forth out of knots three or five broad leaves like unto thoſe of the Maple or Plane tree, ſtanding on ſmall blackiſh long ſtalkes, and are divided in three or five parts, full of veines dented about the edges, and pointed at the ends.

3. *Storax rubra.* Red Storax.

This thing that formerly was called *Storax rubra*, was a barke of ſome kind of tree, and thought to be the *Naſcaphthum*, or *Naſcaphtum* of *Dioſcorides*, but *Cordus* on *Dioſcorides* ſcanning the matter ſomewhat more ſeriouſly determineth it to be a thing utterly unknowne to him in his time, and by the cheapeneſſe of that barke that went under that name, ſaith plainely it was too cheape to be right, *Dioſcorides* making *Naſcaphthum*, to be like the barke of the Sycomore tree, as ſome coppies have it, or the Mulberry tree as others and brought from *India*, being of a ſweete or pleaſant ſent in fumigations as well by it ſelfe as mixt with other perfumes: but *Matthiolus* taketh *Naſcaphthum*, to be that which was called *Tigname* in ſhops, which as he ſaith the *Italians* called *Agallocho*, that is *Lignum Aloes*, and ſo *Cordus* alſo ſaith, that one *Iohannes Rodericus* a *Portugall* tooke the *Naſcaphthum* to be that which in their ſhops was called *Palo daguilla Lignum Aquilæ*, that is the ſame with *Lignum Aloes*, as aforeſaid, but *Cordus* miſliketh that opinion, the *Lignum Aloes* being a wood and the *Naſcaphthum* a barke, yet although this long diſcourſe be ſomewhat from the matter in hand, yet ſeeing it fell ſo fitly to ſpeake of *Naſcaphthum*, I could not doe otherwiſe then ſhew you what others have thought thereof, in that as I ſaid divers tooke it to be *Storax rubra*, when as no auncient Authour mentioneth it: but both *Serapio* and *Avicen* divide *Styrax* into *liquida* and *ſicca*, by *liquida* underſtanding the pure gumme flowing from the tree, and not that *liquida* which

which we have now adaies by that name, and by the *ficca*, the *fæces* of the expressed oyle from the fruite, but some of our modernes take the *Calumita* to be *Rubra*.

*The Place* and *Time*.

The first groweth in *Provence*, of *France* in *Italy*, *Candy*, *Greece*, and other these hither parts of *Turkie*, where it yeeldeth no gumme, but in *Syria*, *Cilicia*, *Pamphilia*, *Cyprus*, and other of those hotter Countries, it giveth much, but is so adulterated that I thinke scarse none in our age hath seene any sincere come over unto us, as by that sincere stuff, that which we have drawn out of the best gumme we could get, is plainely to be discerned, so much grosse *fæces* remaining behind, after the expression, and by the comparing of it with *Dioscorides* his notes: It flowreth in the Spring, yeelding fruite in *September*, the other *Bauhinus* as I said, had it from *Bellus* of *Candy*, but where it grew is not signifyed.

*Styrax arbor vulgaris.* The Storax tree.

*The Names*.

It is called in Greeke στύραξ, and in Latine *Styrax arbor*, as the Gumme is called *Gummi Styrax*, or *Storax*, and in shoppes *Storax* or *Styrax Calamita*, which for what cause it was so called, *Galen* declareth, that because the best and most sincere came from *Pamphilia*, they used to put it into Canes, the better to preserve, not onely the sent as most say, but even the substance too, as I thinke, for the pure sincere gumme is so piersing that no barrell can be made so close, but that it will search the joynts, and draine through them, which opinion of mine although it may seeme strange, as not being heard of before, yet I have many reasons both to induce me therunto, & some to contrary theirs that object the transportation of handfuls of *Dictamus*, in Canes or Ferula stalks in the like manner, which are of far differing natures: the one a dryed herb, which needed not any such inclosure, to preserve the sent, whereof it hath not so much that they needed so to put it up for feare of loosing, and besids the cask was so smal that abundance of them could containe but a little merchandize, some other cause they had surely, if they did put them, the leaves and stalkes I meane, into the Canes (whereof I somewhat doubt, but that they put them rather with Canes to keep them from breaking) & this other a gum that required some tight cask to containe it, for feare of leaking, and the Cane between the joynts, as not having any chinke, was the fittest with them I thinke to containe it, and thereof I thinke came the name of *Calamita*, to confirme which opinion, I have found the sincere gumme of Storax, which I have by Art and the presse onely (and not by any distillation) purified and made to be so pure that it would pierce even through a woodden vessell in the heate of Summer, and therefore was forced to keepe the said sincere gumme in a glasse or gally pot, which was so fluent that it would runne upon any small occasion of leaning downe the vessell, a long time after the extracting. There is some doubt also with many, what our *Storax liquida* should be, for none of the ancients have made mention of any such thing: some would have it a kinde of *Storax* from the tree. and to that purpose *Durante* hath figured out a Storax tree, appropriating the *Storax liquida*, to issue from thence, which is besides the text, and more then he can prove: others from the *Arabians* I thinke, take it to be the extraction of pure fat Myrrhe, called *Myrrhæ stacte*, which I cannot see how it should be so, seeing the *Storax liquida*, is of so strong and piercing a sent that no Myrrhe, from whence they say it should be taken hath any the like: it is therefore assuredly some other thing, whereof as yet we have not attained the knowledge, *Bauhinus* lastly in describing this *Styrax folio Aceris*, in his *Prodromus* entituleth it *Styrax liquida*, which how much or little it sorteth thereunto, I know not, the time hereafter may declare. The *Storax rubra*, something hath beene spoken thereof here before, yet some travailers have affirmed that the tree thereof groweth in *Cyprus*, but (unlesse they meane the first Storax tree) untill it be further confirmed, I shall rest doubtfull thereof.

*The Vertues*.

There is no part of this tree in use with us, but the gumme that issueth out of it, and it is hot in the second degree, and dry in the first, it heateth, mollefyeth and digesteth, and is good for coughes, catarrhes, destillations of rheumes and hoarsenesse: it provoketh womens courses, and mollefieth the hardnesse and contractions of the Mother, it gently loosneth the belly, if a little of the true Turpintine be put unto it, and so made into pilles and taken: it resisteth those poysons that kill with coldnesse, as the Hemlocke doth, and the like: a small quantity thereof taken saith *Pliny*, doth drive away sadnesse from the minde, but if it be taken too much or too often, it doth contrarily bring and encrease it, and worketh paine and heavinesse in the braine, and cause troublesome sleepes. Vsed as a pessary it draweth downe mightily, both the courses and the afterbirth, dropped into the eares, it taketh away the singings and noyse in them, applyed to the hippes, shoulders or joynts afflicted with cold aches it resolveth and comforteth much, and is good to be put into the bathing are made for lamenesse in the joynts, and wearinesse by travaile, it is also of good use to be put with white francumsence, to perfume those that have catarrhes, rheumes and defluxions from the head into the nose, eyes or other parts, by casting it on quicke coales and holding their heades over the smoke, and to aire their night caps therewith, wherein they meane to lie: it

dissolveth

diſſolveth hard tumours in any part, as thoſe about the throate called the Kings Evill, and other nodes or tumours in the fleſh or on the joynts: It ſerveth alſo as a perfume to burne in houſes or chambers, either alone or with other things, it is put alſo among ſweete pouthers in bagges, for cheſts and wardrobes.

## CHAP. XCI.

### *Draco arbor.* The Dragon tree.

Muſt needes adde this tree to the reſt of the berry bearing Reſinous trees, becauſe it agreeth with them, whoſe deſcription is on this manner. It is a goodly faire great tree to behold, riſing as high as a Pine tree, with a great body, covered with a rugged barke, full of chappes and clifts, bearing eight or nine great armes, equally ſpreading from the toppe of the truncke or body thereof, each of them bare, for a cubits length, and then thruſting forth at their heads three or foure ſmaller branches, yet of an armes thickeneſſe, and bare alſo for a certaine ſpace, and bearing at the toppes of each of them, divers very long and narrow leaves joyned together at the bottome, and compaſſing one another like as the Flowerdeluces doe, each of them being a cubit in length, and an inch in breadth, growing narrower to the end, where it is pointed with a thicke middle rib, running through the middle, all the length of them, and being reddiſh about the edges, which are ſharpe like the *Iris* leaves, abiding alwayes greene: from among the leaves at the heads, come forth long footeſtalkes, of about a footes length, branched forth into other leſſer ſtalkes, bearing at certaine ſpaces, divers fruites or berryes in cluſters (for the flowers have not beene obſerved) each of them like unto a ſmall Cherry, of a ſowriſh or tart taſte, and of a yellowiſh colour, when they are ripe with a ſtone within them, very like a Cherry ſtone, and a like kernell alſo (but here is no ſhew of any Dragon here in to be ſeene, as *Monardus* fableth, and others that from him have ſet it forth, which ſheweth how neceſſary it is to have judicious and conſcionable men to be the firſt relators of ſtrange or unknowne things) out of this tree being ſlit or bored, commeth forth a thicke (not cleare as *Matthiolus* ſaith) darke red gumme or Roſſin, which hardneth quickely, and will melt at the fire, and flame being caſt therein, yet ſomewhat dryly, being bruiſed it ſheweth a very orient red crimſon or bloody colour, yet is very hardly mixed with any liquour, eyther water or oyle: the wood is very hard and firme, and hardly admitteth to bee cut: but the younger branches are more tender. What if Maſter *Hamonds* fleſh tree, growing in *Magadaſtar*, ſet forth in his Paradox, yeelding liquor like blood, may not prove to be this tree, if the tenderneſſe of the wood, cutting as he ſaith like fleſh, either hinder not the identity, or be not an hyperbole.

*Draco arbor.* The Dragon tree.

*The Place* and *Time.*

This tree groweth in the Iſlands both of *Madera*, and the *Canaries*, and in *Braſſil* alſo, as I am given to underſtand, where it groweth vaſt, but *Cluſius* ſaith that he found it in the Orchard, belonging to the Monaſtery of our Lady of grace in *Spaine*, planted among ſome Ollive trees on a ſmall hill: the Time is not expreſſed. This is ſo tender, that although it hath ſprung with us from the ſtones that were ſet, yet it would ſcarſe endure to the end of Summer, but periſhed with the firſt cold nights.

*The Names.*

It is moſt probable that neither *Dioſcorides* nor any of the ancient Greeke or Latine Authours had any knowledge of this tree, or could give any deſcription thereof, but of the gum or Roſſin onely, yet neither knew whether it came from herbe or tree, or was a minerall of the earth, but called it κιννάβαρις in Greeke, and thereafter *Cinnabaris* in Latine, *Dioſcorides* ſaith that it was ſo ſcarſe to be had, that the Painters could not get ſufficient for their workes, but yet ſaith ſome called it *Sanguis draconis*, ſo ancient is the name, and by which onely the moderne Writers are led to thinke that the gumme of this tree continuing the name to this day, the reſt of this declaration agreeing likewiſe thereunto, is the right *Cinnabaris* of *Dioſcorides*: but *Pliny* in his 33. Booke and 7. Chapter, for the elder world hath fabled (no leſſe then *Monardus* from his Biſhop of *Carthage* in this as is aforeſaid) and ſet it downe for a truth that *Cinnabaris*, is no other thing but the blood of a Dragon or Serpent cruſht to death by the weight of the dying Elephant killed by him, and that both their bloods mingled togethers, was the *Sanguis draconis* that the Painters uſed, and was alſo uſed in medicines. *Iulius Solinus* alſo affirmeth the ſame thing: but aſſuredly the true cauſe of the name hereof was the bloody colour that the gum gave, however they coloured the truth from others knowledge by the name of a Dragon.

*The Vertues.*

There is no part of this tree put to any uſe in Phyſicke with any that I know, but the gum onely, yet no doubt in

in the naturall places, or where it groweth, both barke and fruite might be applyed for such like diseases as the gumme is put unto, which is very astringent, serving to restraine the fluxe of blood or humours, from any parts, both in man and woman, as laskes, the menstrues whites, and the gonorrhea: it is also said to helpe the strangury, and stoppings of the urine, to fasten loose teeth, and is very availeable for the gummes are spongy or with loose flesh: it is good also to stay the watering of the eyes, and to helpe those places that are burnt with fire: The Goldsmiths and Glasiers use it much in their workes, the one for an enamell, and to set a foile under their pretious stones, for their greater luster; and the other by fire to strike a crimson colour into glasse, for Windowes or the like. I doe not know that Painters can bring it to be a fit colour to be used in their workes.

## CHAP. XCII.

*Cedrus magna Conifera Libani.* The great Cedar of *Libanus*.

THe rest of the *Arbores resiniferæ*, those trees that beare Rossins are to follow, which are these that beare Cones, being the great Cedar, the Pine tree, and all the sorts thereof both tame and wild, the Pitch tree, the Firre tree, the Larch tree, the Cypresse, and the *Arbor vitæ*, or tree of life: and first of the great Cedar. This great Cedar groweth up with a great thicke upright body, taller then any other tree whatsoever stored with branches on all sides, but so ordered that the lower branches spread largest, and still upward they grow smaller up to the toppe, representiug the forme of a Pyramid or Sugar loafe, to them that view it a farre of; the greater and lowest branches with the body are somewhat rugged and full of chappes, but that of the upper branches is very smooth, and of an ash colour, and being rubbed away with ones nailes, appeareth greene underneath, and reddish under that: the branches some say grow all upright, but others straight out, and as it were crosse wise, strong, but brittle, and easie to be broken, not to be bended and so placed about the body, one above another that they yeeld an easie ascent up to the toppe, as it were by steps: the leaves grow many together, out of a knot, which are small long and narrow, like unto those of the Larch tree, somewhat hard, but not sharpe at the end as they are, and so set, the longest being in the middle, and the lesser on the sides, that they represent the forme of a Painters pensell, abiding alwayes greene on the trees, being somewhat sweete in sent, a little sowre, bitter and astringent in taste: it beareth Cones that grow upright like as the Firre doth, not hanging downe as others doe, slenderer then those of the Pitch tree, and thicker, greater, and harder then those of the Firre, somewhat yellowish and round at the end, made of many scales, with a short footestalke to it, but so firmely set to the branch, that without breaking away some of the wood of the branch, it cannot be pulled away, yet the scales opening of themselves, will fall away, leaving the stalke bare that went through the middle of them, but this it will not doe untill the next yeare after it be ripe, for it requireth one whole yeare to ripen, within which is the seede, as bigge as Grape kernells, somewhat sweete in taste, bedewed with an oylie substance, that is of a good sent: out of this tree there commeth two sort of Rossin called *Cedria*, the one thinne like unto that of the Firre tree, which commeth forth by piercing the tree at the sundry knots while they be young and not covered with a rugged barke, and putting thereto an horne, out of which it must runne: the other Rossin floweth forth of it owne accord, growing hard of it selfe thereon, which will sticke so fast to the teeth if it be chawed, that it will hardly be pulled away againe, and being smelled unto giveth a very sweete sent; the Wood is durable above all other, and not in many ages yeelding to corruption.

*Cedrus magna Conea Libani.*
The great Cedar of *Libanus*.

*The Place* and *Time*.

This Cedar groweth on sundry mountaines in *Syria*, and the parts neere thereunto, and the coldest parts of them that are covered with snow as *Amanus*, *Taurus* and *Libanus*, and not in many places else that have beene observed, the time is declared in the description to be a whole yeare in perfecting the fruite, and as *Pliny* saith, new come forth before the old are ripe.

*The Names.*

This Cedar is called in Greeke κέδρος (not knowne to *Dioscorides*, *Galen* or *Pliny*, as their workes testifie, for theirs is the *Oxycedrus*, that beareth berries like to Iuniper, or the Mirtle) and κέδρελατη *quasi Cedrabies*, be cause it groweth high, like the Firre, *Theophrastus* calleth it κέδρος φοινικὴ *Cedrus Phœnicea*, which *Gaza* unfitly translateth *Punica*, and in the *Geoponickes Dendrolibanus*, *Cedria* you have heard before what it is, namely Rossin that floweth out of the tree, when it is bored or peirced, as in the Firre and other trees: but *Cedrium*, which some call

*Cedrelaum*

*Cedreleum* or *Cedreoleum* is the first liquid substance that commeth out of the stickes, while they are in the burning (such as we call tarre, that is, the liquour of the Pine and Pitch tree stickes when they burne) before the hard Pitch commeth forth, with which as well as with the *Cedria*, in former times the *Egiptians* embalmed the bodies of the dead, to cause them to abide for ever uncorrupted: but many Writers confound these and the Pitch of the Cedar together, that issueth out in the burning after the first, calling them *Cedria*, when as they are divers. The *Arabians* call the tree *Serbin*, (and the Rossin or Tarre *Kitran Alkitran*; and *Ketran*) the *Italians Codro*, the *Spaniards Cedro*, the *French Cedro*, and we Cedar. *The Vertues.*

There is no part of this tree put to any Physicall use, but the *Cedria*, or Rossin that commeth out of it which is hot in the fourth degree, and preserveth the dead bodies from rotting, and therefore was called the life of the dead, and the death of the living, because if it be laid on garments or skins, it will burne and consume them: yea and to the tender flesh of the living, it will worke like a causticke: yet is it effectuall to cleare the sight from filmes or skinnes that are growne over it, and taketh away the scarres of wounds and sores, and mixed with a little vinegar and dropped into the eares, it killeth the wormes, and with the decoction of Hyssope, being put in taketh away the noyse and humming in them, if a little of it be put into an hollow tooth it easeth the paines, and breaketh the tooth, if it be mixed with a little vinegar, and they washed therewith it will doe the like: it helpeth the disease of the throate called the Quinsie, and killeth both nits and lice: it resisteth the poyson of the Sea Hare taken in sodden Wine, and if it be laid with salt on the biting of the venemous serpent called *Cerastus*, it will helpe it: it helpeth the leprosie also, if it be either annointed or taken inwardly, and purgeth the ulcers of the lungs, and healeth them if a small quantity thereof be taken: it also helpeth the itch and scabs in man or beast, it killeth the living childe in the mothers body, and expelleth the dead, and taketh away all hope of conception if the privy parts be touched therewith.

## CHAP. XCIII.

### *Larix.* The Larch tree.

THe Larch tree groweth oftentimes as high as either the Pine or Firre tree, but most usually lower, covered with a very thicke barke, rugged and full of chappes, and reddish on the inside, the branches grow one above another, in a comely order, having divers small yellowish knobs or bunches set at severall distances, from whence doe yearely shoote forth many small thicke long and narrow, soft and smooth greene leaves, as it were in a tuft together, like the former Cedar, but shorter, smaller and blunter pointed then the leaves of either Pine or Firre tree, which doe not abide any Winter as they doe, but fall away as other trees that shed their leaves, and gaine fresh every Spring (which is peculier to this alone, among all the other kindes of Rossin-bearing trees) the blossomes are very beautifull and delectable, being of an excellent fine crimson colour, and very sweete, which afterwards turne into small soft cones, like unto Cypresse nuts while they are close, but longer then they, made of many fine and thin small scales, one lying upon another, standing on a short stalke, having small seede on the inside of every scale, formed like a small Bird, with two wings, and a small sweete kernell within them like the Pine kernell: the wood is very firme, hard, and close; long in growing and long lasting, and maketh the best coales for all Smiths worke, and for Miners to melt the Ore of mettall, above any other wood to hold fire longest and strongest, although *Pliny* saith, *lib.* 16. *c.* 10. that it burneth no other wise then a stone, nor maketh any coales, which how it can bee, that a Rossinous tree should not burne any may judge: it yeeldeth forth a liquid Rossin being bored, very cleare and white, which we call *Venice* Turpintine: there is also found upon the bodies, and greater boughes hereof, a kinde of hard and dry Mushrome, called *Agaricke*, whereof I have spoken with the Turpintine of this tree, in the second Classis of this Booke, which is of purging Plants.

*Larix.* The Larch tree.

*The Place* and *Time.*

It groweth not in all *Greece*, for neither *Dioscorides* nor *Theophrastus*, hath made any mention thereof, but most plentifully in the Woods by *Trent*, and in all that tract betweene *Germany*, and *Italy*, and many other places of *Germany*, it shooteth forth as is said young leaves every Spring, with the blossomes presently after, and ripeneth the fruite before Winter.

*The Names.*

It is called in Greeke λάριξ, and the Turpintine ῥητίνη λαρικίνη, in Latine also *Larix*, and the liquid Rossin *Resina Laricea*, or *Larigna*, or *Terebinthina Venetia*, *Pliny* faulted many times in mistaking the πίτυς *Picea* of *Theophrastus* for this, applying those things to the *La-*

*rix*, which he doth to *Picea*, as *Lugdunensis* sheweth very amply. *Vitruvius* also erred with *Pliny*, in saying that the wood of the Larch tree did burne no otherwise then a stone in the fire: that *Fuchsius* also was in an errour: *Matthiolus* sheweth, that thought the *Venice* Turpintine was taken from the Firre tree, for he protesteth that upon his owne knowledge and sight, it came from the Larch tree, he also insisteth against *Brasavolus*, that thought other trees had produced *Agaricke*: but those of other trees were hard Mushromes, such as we call Touchwood, which serveth like tinder to receive fire strucke from the flint, &c. all Authours call it in Latine *Larix*, the *Italians* and *Spaniards Larice*, the *French Melese*, the *Germanes Lerchenbaum*, and we the Larch tree.

*The Vertues.*

I have spoken so sufficiently of both Turpintine and Agaricke, in the second Classis of this Worke, that I can adde nothing more thereto, and therefore to prevent a double repetition of the same things, I must referre you thereunto.

## CHAP. XCIIII.

### *Pinus.* The Pine tree.

THere are many sorts of Pines, some tame some wild: of the tame kinde there is observed little variety: but of the wild much, for some grow on mountaines farre distant from the Sea, others on the hills and places neere the sea, of all which, although they be many, I would make but one Chapter, and not separate them into any more.

1. *Pinus urbana sive domestica.* The manured Pine tree.

The tame Pine tree groweth very great and high, with a thicke reddish coloured barke, spreading large armes towards the toppe, and they againe divided into other lesser, whereon are set by couples together at a joynt or knot all along the branches, close one unto another, long narrow or almost round, hard and sharpe pointed, pale greene leaves, abiding continually on the young branches, and not falling away but from the elder: this beareth certaine small yellow catkins in the Winter, which fall away in the Spring as the cones encrease: the fruite or cones, that are somewhat long and round, grow very high on the branches, and are somewhat greater then in any of the other sorts, composed of sundry hard and browne wooddy scales, lying close one unto and upon another, which when they open of themselves, or are caused by the heate of the fire, doe shew within them certaine hard shels, which containe in each of them, a long and whit every sweete kernell, covered with a very thin reddish skinne, that is easily rubbed of; the wood hereof is firmer, heavier and closer grained then of the Firre or Deale, reddish also, and not so short or brittle as it is, and with a kinde of moisture about the heart. This is not so plentifull in yeelding either Rossin or Pitch, if it should be so ordered as the wilde kindes.

1. *Pinus urbana sive domestica.*
The manured Pine tree.

2. *Pinus sylvestris montana fructifera.*
The fruitefull wilde Pine tree.

3. *Pinus sylvestris altera fructifera Teda arbor sorte.* The soft sheld wilde Pine tree.

4. *Pinus sylvestris humilis in fructifera.* The low wild barren Pine tree.

Of this kinde some make another sort, whose conē or apple is somēwhat longer.

*Altera cono oblongiori.*

2. *Pinus sylvestris montana fructifera.* The fruitefull wilde Pine trēe.

This wild Pine groweth seldome so high, but very like unto the former tame kinde, being no otherwise to be distinguished from it, but that it groweth of it owne accord upon hills and mountaines, and that the barke thereof is thicker and rounder, and the leaves somewhat shorter, harder, more prickly, and of a sadder greene colour, and the cones or fruite smaller, but have as good and sweete a kernell within them as the former, and contained in as hard a shell.

3. *Pinus sylvestris altera fructifera Teda arbor sorte.* The soft sheld wild Pine tree.

This other wild Pine groweth great in size, and large in body, but yet not of that heighth as the other, neither is the barke reddish nor so thicke, but darker and pliable: the leaves also are like, but grow thicker on the branches, even foure or five at a knot or joynt, and the tree fuller of branches, but more crooked and full of sappe, and end in a pensill-like forme: the cones are small and short, not much bigger then those of the Pitch tree, of a darke purplish colour, full of Rossin, but softer, and the shels within them easie to be broken betweene ones fingers, the kernells likewise being very tender and short, and sweete, like unto those of the tame Pine, but a little harsher, as the taste of most wilde fruites are, in comparison of the manured. This kinde doth more frequently corrupt with the abundance of the sappe, which is the Rossin, then almost any other sort.

4. *Pinus sylvestris humilis infructifera.* The low wild barren Pine tree.

This wilde Pine tree riseth up with little or no body at all, but shooteth forth very long armes round about, like unto pipes, from whence peradventure it was named *Tubulus* being ten, and sometimes fifteene cubits long, whereof some call it also *repens*, being slender and without knots, or branches, of which are made hoopes to binde caskes, because they are so smooth and so flexible: the cones are not bigger then the last, but have no kernels within them that may be eaten, and therefore called *infructifera*, barren or fruitlesse, and not because it beareth not cones or fruite.

5. *Pinus sylvestris sterilis elatior.* The taller barren wilde Pine tree.

This tree hath a single blackish roote, that shooteth downe into the ground like a stalke, the body whereof is often crooked and writhen, covered with a reddish barke, but the branches are smooth, and easie to be broken, being thicke bushing at the toppe, the leaves are slender and hard, and but two at a knot or joynt, somewhat writhed at their first springing, and tasting harsh and somewhat sower: the cones are but small and without any ēdible kernells like as the last is.

6. *Pinus maritima major fructifera.* The greater Sea Pine trēe.

This greater Sea Pine riseth to a meane height, with a crooked body, and for the most part spreading into branches from the ground, the leaves are somewhat long, and like the first wilde kinde, but shorter and greener, the cones are somewhat lesser, longer, and whiter, with much Rossin often on them, the kernels whereof are like unto them, but covered with a blacke skin. *Clusius* hath set forth another sort hereof, whose figure I here give you.

6. *Pinus maritima major fructifera.*
The greater Sea Pine tree.

6. *Pinus maritima major fructifera altera Clusij.*
Another sort of the greater Sea Pine tree of *Clusius*.

7. *Pinaster maritimus minor.*
The lesser or dwarfe Sea Pine tree.

8. *Pinaster pumilus montanus.*
The dwarfe mountaine Pine tree.

7. *Pinus maritima minor.* The lesser or dwarfe Sea Pine tree.

The lesser Sea Pine scarse riseth to the height of a man, full of more slender and pliant branches then the former, not covered with so rugged a barke, nor spreading so much, the leaves are very slender, shorter and not so hard: the Cones are likewise lesser and slenderer, and so are the kernels also, and covered with a blacke skinne.

8. *Pinaster pumilio montanus.* The dwarfe mountaine Pine tree.

This dwarfe Pine riseth to a mans height, branching forth from the ground into somewhat large armes, and covered with a thicke rugged barke, spreading about: the leaves stand by couples, as in divers of the other sorts but thicker shorter and blunter pointed, and of a sadder greene then in the first wild kinde, the cones are small little above an inch long, not much bigger then the Larch tree cones, but more round at the head, and smaller at the end, standing upright, and not hanging downe as all the others, the shell of the nut within is winged as many are, but the kernell is small and hard.

9. *Pinaster tenuifolius julo purpurascente.* The crooked mountaine Pine with thin leaves.

The body and branches hereof are crooked or writhed and not streight, the leaves thereon are very thinne, and shorter then many others, two joyned together round about the branches, at the ends whereof come forth certaine small scaly catkins of a purplish colour which fall away into a small pouther, and after them come in the middle a new sprout of leaves, inclosed in a certaine skin: the cones hereof are small and blunt pointed.

10. *Pinaster niger latiore folio julis pallescentibus.* The crooked mountaine Pine with broader leaves.

This other crooked Pine hath such a like body and branches as the last, spreading much, and with a sadder barke, the leaves are broader also, sharper pointed and shorter then they, and of a darker greene colour; the catkins comming forth at the ends of the branches like the last, are of a yellowish greene colour, and not purple as they are, after which come new leaves in the like manner: the cones are smaller then they.

*The Place* and *Time.*

The first tame kinde is found planted in sundry places of divers Countries, for the beauty of the tree with his ever greene leaves, yet are they found also wild about *Ravenna* towards the Sea side. The other sorts grow both in *Spaine*, *Italy*, and *Germany*, and the parts neere adjoyning, and the Sea kindes neere the Sea, in many places and upon the Land also as *Clusius* hath observed: the catkins of many come forth in the Winter, and fall away in the Spring: others spring not untill *May*, the fruite of some of them being ripe in the end of Autumne and others, not of a yeare after the springing.

*The Names,*

The Pine tree is called in Greeke πεύκη, in Latine *Pinus*, the Cones are called κῶνοι, in Latine *Coni*, and the auncienter Greekes φόβιλοι, but now the kernels are so called, the kernels within them πιτυίδες, *Pityides*, as *Dioscorides* saith, who calleth both those of the Pine and of the Pitch tree by that name, whereof *Matthiolus* is in some doubt that the place is erronius, the word Pitch tree being thrust into the Text without any ground of reason: for πιτύιδας are τῶν πίτυων καρπόν, as φόβιλοι be τῶν πευκῶν *Pinorum fructus*: and the kernells onely of the Pine tree are edible, and not the Pitch tree. That πεύκη which *Theophrastus*, *Dioscorides*, and *Galen* sheweth, should be the Pine tree, and not the Pitch tree, may be shewed in divers places out of *Galen* and others, although *Pliny* doth mistake them, from the likenesse of *Peuce* to *Picea*, and *Pitys* to *Pinus*, as also *Peuce* to *Larix*; and *Bellonius* from him doth so also, and *Gaza* sometimes translateth them right, and sometimes wrong, but there may be as much doubt, what tree *Dioscorides*, and *Theophrastus* meant by πίτυς, whether the Pitch as it is thought by the most judicious or some sort of Pine, because *Dioscorides* putteth them both together in the title of the Chapter, as if they were both of one kinde, and yet saith some held them to be divers sorts, and nameth the fruite of them both by one name as is shewed here before, when as it is plainely knowne to all that have observed them, that the Pitch tree doth more resemble the Firre then the Pine, as being no other difference betweene them, the Pitch and the Firre, then betweene male and female, as I shall shew you after a while, and there is greater difference betweene the Pitch and the Pine tree, then there is of the Pines among themselves: and *Theophrastus* also in many places of his Bookes nameth πίτυς ἀγρία, as if there should be two sorts of Pitch trees, a tame and a wild, which is not found in him to be so distinguished, as he doth of the Pine: I know to mend this matter, that *Lugdunensis* sheweth the reading of πίτυς ἀγρία, to be understood *picea*, *aquifolium*, two words in his judgement, but how those two words should be so often joyned together in him, I see not unlesse they were meant one thing. *Matthiolus*, findeth much fault with *Pliny*, that maketh *Teda* his sixth kinde of Pine tree, taxing him for errour for it, for that *Theophrastus* and others make *Teda* to be but the peculiar fault or corruption of the Pine tree of what kinde soever, that is suffocated and killed with the abundance of it owne fatnesse, not suffering the sappe to rise that should nourish it, and then serveth for lights as Torches, slived out into shivers, the cause whereof *Theophrastus* sheweth *lib.6 caus.cap.*15. as he did *lib.*3 *hist.c.*10. what *Teda* is, but other good Authours shew that although *Teda*, be so taken with *Theophrastus* and others, yet that letteth not, but that there might be also a tree peculiar that bore the name of *Teda*, it being *homonomia*, a word of divers significations, and that else *Pliny* was not in his right senses, to appoint it a peculiar kinde, and knew it was appropriated to corrupt trees also, as himselfe declareth in many places of his Bookes. The first here set downe is called *Pinus urbana*, *domestica*, *sativa*, and *vulgatissima* by all Authours that have written thereof. The second is called *Pinus sylvestris fructifera*, or *montana*, or *Pinaster* likewise by all Authours. The third is the *Pinus sylvestris Cembro* of *Matthiolus*, which *Lugdunensis* calleth *Teda arbor Plinij*, as he maketh the computation, and his *Pinus Tarentina* also. The fourth is *Matthiolus* his *Mugo*, and the *Pinus tubulus Plinij* also of *Lugdunensis*. The fifth is the *Pinus sylvestris sterilis* of *Lugdunensis*, but is not the *Pinus maritima Theophrasti* of *Lobel*, nor the *maritima major* of *Lugdunensis*, for these are the next or sixt, that is *Pinus maritima major*, although *Bauhinus* putteth them all under one title, and the other of this kinde, is another sort thereof that *Clusius* hath set forth. The seventh is the *Pinus maritima minor* of *Dodonæus*, and *Bauhinus*, and the third *Hispanicus* of *Clusius*. The eighth is *Clusius* his *Pinaster pumilio*. The ninth his *Pinaster tertius Austriacus*. And the last is his *Pinaster secundus Austriacus alter* or *niger*. The *Arabians* call the Pine *Senabar*, the *Italians* and *Spaniards Pino*, the *French Pin*, and the kernells *Pignons*, the *Germanes Hartzbaum*, and *Fichtembaum*, and *Fijnholtz*, the *Dutch Pinappelboom*, and Wee the Pine tree, or Pine Apple tree.

*The Vertues.*

The barke of the Pine tree is binding and drying, staying the laske and provoking urine: it helpeth the frettings and gallings of the skin, ulcers also that possesse the upper parts, and burnings with fire, taken with *Ceratum Myrtinum*, or with *Litharge*, and skinneth them after, and mixed with Coperas, it stayeth the fretting or creeping of ulcers, the fumes thereof taken underneath, causeth a delivery of the birth, and expelleth the secondine: the leaves are cooling and asswage inflammations, and keepe ulcers from being inflamed, a dramme of them taken in water or mede, that is honyed water, are good for the heate of the Liver; if they be boyled in vinegar, and gargled warme in the mouth, it helpeth the paines in the teeth and gummes, the like doth the shivers of the Torchpine boyled in vinegar and gargled. The kernells of the Apples are wholesome, and much nourishing while they are fresh, and although they be somewhat hard of digestion, yet they doe not offend, especially if they be steeped three or foure houres in warme water, before the taking, to soake out their sharpenesse and oylinesse: those that are of hot constitutions may take them with Sugar, but those that are cold with hony, and so they doe amend the putrefying humours in the stomacke and bowels, and stir up bodily lust and encrease sperme, if they be made into an electuary with a little pouther of *penidij pennits*, and some sweete wine, also they much helpe an hoarse throate, wheesings and shortnesse of breath, and when the voyce is lost, and expectorate flegme, and are good for an old cough, and the ulcers of the lungs: they also lenifie the uritory passages being fretted with the stone, and cause them to be easily avoyded: they helpe also to ripen inward Impostumes, and are singular good for macilent bodies, to hearten them and make them grow fat, being often taken they helpe the palsie, shaking, and numnesse of the members. Both Comfitmakers, and Cookes know how to make dainty *Quec choses* for their delight that will have them. There is a water destilled from the greene cones or apples that is very effectuall to take away the wrinckles in the face, to abate the over swelling breasts of Maides, by bathing them with wet cloathes in the water laid on them, and to restore such as are ravisht into better termes.

## CHAP. CXV.

### *Picea.* The Pitch tree.

THe Pitch tree hath formerly beene comprehended under one kinde, yet *Pliny* seemeth to reckon a *sativa* and a *sylvestris*, the *sativa* to be *Sapinus*, and the *sylvestris Picea*: but we in these times knew but one sort until *Clusius* hath added a dwarfe sort thereunto.

1. *Picea vulgaris.* The ordinary Pitch tree.

The Pitch tree is so like unto the Firre tree that it oftentimes deceiveth them that are not skilfull

*Picea.* The Pitch tree.

2. *Picea pumila.* The dwarfe Pitch tree.

Or

or well excercised therein, for it is to be discerned but by some especiall notes. It riseth up as high and groweth as great as the Firre, steeple fashion, with a thicke reddish ashcoloured barke, rough and tough like leather, and spreadeth the branches a crosse as that doth, but bending downe, not standing upright as the Firre doth: The leaves also are thicke set on all sides of the branches, and not onely on two as the Firre: being thicke and short, round, and not flat as the Firre leaves are, softer also and not hard, pointed at the ends like it: the cones come forth at the ends of the branches, after the catkins are fallen, which are somewhat reddish at the first springing forth, and being full growne are slender, about seven or eight inches long, bending downewards, abiding so long on the trees, untill the scales opening, the seed within them which is small and blackish, falleth out upon the ground, the wood is smoother, softer, lesse knotty, and with fairer and straighter graines, and thereby more accepted in workes then the Firre, from this tree is gathered small peeces of white hard dry Rossin, distilling out thereof of it owne accord, very like unto *Olibanum*, that many may be deceived with it, as also a liquid Rossin or Turpintine, by boring the tree as others are, and Pitch also, as from the Pine.

2. *Picea pumila*. The dwarfe Pitch tree.

This tree never riseth high, but alwayes abideth low, spreading the branches in manner of a crosse as the former, beset with shorter and paler greene leaves all about them; this beareth certaine small heads, of the bignesse of an Hasell nut, composed of scales laid close one upon another, whose end is a prickly leafe, which opening when it is ripe sheweth it to be like hollow voyd or empty places within, and from the heads that are at the ends of the branches, shoote forth oftentimes branches with sundry short and prickely leaves: whether it bore either flowers or fruite, *Clusius* saith he knew not, for he saw none on any that he found.

*The Place* and *Time*.

The first groweth usually in all Countries with the Firre trees, but seldome neere the Sea: the other *Clusius* found in his search for simples in *Germany*, but nameth no place: The Pitch tree blossomes fall away in *March* and *Aprill*, when the cones begin to come forth, which are ripe before Winter, but abide on as is said, if they be not gathered, untill it shed all the seede, and that the windes and the weather have rotted and blowne downe the stalkes of the withered.

*The Names*.

It is called in Greeke πίτυς, and in Latine *Picea*: because the pitch is made of this tree yet, as all Authours doe agree, the Pine tree is most usually taken for that purpose, and of it is made both the best and the most store. *Bellonius* as *Clusius* thinketh was much deceived in the Pitch tree, taking the wilde Pine tree for it, in his second Booke and third Chapter, where *Clusius* noteth it, giveth it the figure of his Pitch tree, which is the wilde Pine tree as he saith, but *Bellonius* in his first Booke and 44. Chapter, doth there give the figure of the *Sapinus*, which he saith some *French* men call *du Sapin*, and some *de la Suiffe*, which as *Lugdunensis* saith, is the name by which they call the Pitch tree, so that it seemeth probable that *Clusius* hath herein mistaken *Bellonius*, yet he saith in the said second Booke and third Chapter, that the Inhabitants doe take *Teda*, Torches from this tree, and that they make pitch, and *Cedria*, Tarre from it also, which is most usually made of the wilde pine tree, but if pitch were not made of this tree, it had the name of pitch tree given it in vaine: πιτυοκάμπαι *Pityocampæ*, are taken to be called *Erucæ painorum*, when as they onely grow on this tree. The *Arabians* call it *Arz*, but *Tragus* saith, they call the Pine tree by that name also, the *Italians Pezzo*, the *Spaniards Pino negro*, the *French Pesse* and *Soiffe*, the *Germanes* have no other distinct name then *Thannenbaum* to call it by, by which also they call the Firre tree, onely they call it *Schwartz oder rot Thannenbaum*, which *Tragus* calleth *Abies rubra*, and thinketh it to be *Picea*, the *Dutch Peckboom*, and we Pitch tree.

*The Vertues*.

The properties hereof are wholly attributed to be the same with the Pine tree, as is before said, both for the barke and the leaves, but this not having any kernels, that are fit either to be eaten or used in physicke, we can say nothing of them.

---

## CHAP. XCVI.

*Abies*. The Firre tree.

ALthough *Bellonius* and *Dodonæus* from him, doe follow *Theophrastus* and make two sorts of Firres, a male and a female, yet unlesse the Pitch tree may be accounted his male, I know not how it may be granted in our dayes: which if it be as *Clusius* and others seeme to yeeld unto, I marveile then what tree his πίνης shall be. I have therefore but one sort of Firre to shew you, although I know some by the smoothnesse and colour of severall sorts of the wood, might argue them of differing sorts, yet I hold that not sufficient to make a severall species, no more then is seene in our Oake, which growing in some places will be smoother or rougher, tougher also or more brittle, of a paler or yellower colour, and with more or lesse veines therein then in others, which commeth to passe by the moist or dry, stiffe or sandy grounds wherein they grow. It groweth taller then any other, except the great Cedar, growing straight up to a great height, without either branch or knot, and covered with a rough hard brittle gray barke, the greater armes stand alwayes foure together, one opposite unto another in forme of a crosse, and grow upright, the side branches on the younger standing but by couples: this order it holdeth in all up to the toppe which is smallest, having risen like a *Pyramis* by degrees: the leaves that grow on the elder branches, stand without order, and are harder yet bluntly pointed, then those on the younger, which stand but on two sides, making the branches seeme flat, and very thicke set one unto another, like the teeth of a combe, and these of the younger growth are flatter then of the elder, oftentimes forked at the ends, of a pale fresh greene on the upper side, and grayish underneath, and smallest towards the ends: the agglets or catkins that this beareth, are small and of a whitish yellow greene, enduring a whole yeare on the trees, after they have shewed their flowers: the cones or Apples thereof, are greater then those of the Pitch tree, and with broader scales, blunt or in some double pointed, on the inside of every scale almost lyeth a small seede, joyned to a thinne skinne like a wing, and abide greene untill Winter, and then grow ripe

ripe, but alwayes ſtand upright, and yeeld much Roſſin in the Summer, but being wounded yeeld a yellowiſh cleare Turpintine, which is ſharper then that of the Larch tree, and fit onely for outward medicines: the wood hereof is ſoft and ſmooth, with many fouldes, and the knots are the hardeſt in any Timber.

*Abies.* The Firre tree.

*The Place* and *Time.*

This tree groweth in all the Countries of *Germany*, *Polonia*, *Denmarke* and *Muſcovia*, and in divers other Countries alſo in *Italy*, *Greece*, *&c.* in *Scotland* alſo, as I have beene aſſured, but not in *Ireland* or *England*, that I can heare of, ſaving where they are planted, and whether there were ever any growing naturally in *England* at any time heretofore is almoſt out of queſtion: The time is declared before.

*The Names.*

It is called in Greeke ἐλάτη, and in Latine *Abies*, and ſo called by all Writers without variation, but that *Cluſius* and ſome others make it to be the *Abies fœmina* of *Theophraſtus*, as they would make the Pitch tree his *mas*, yet as I ſaid *Bellonius* and *Dodonæus* doe ſhew us another tree to be his *mas*, which yet is ſo like the Pitch tree, that if it be not it, we know not what to make it. *Bauhinus* alſo conſenteth unto them, and yet he calleth the *mas*, *ſurſum ſpectantibus conis*, when as their figure ſheweth them to be *dependentobus*. The *Italians* call it *Abete*, the *Spaniards Abeto arbol*, the *French Avet*, *Sap*, and *Sapin* alſo in ſundry provinces thereof, yet *Pliny* ſaith the lower part of the Firre is called *Sapinus*, and the knotty upper part *Fuſterna*, the *Germanes* as I ſaid *Thannenbaum* and *weiſz thannenbaum*, the *Dutch Dennemboom*, and we in *Engliſh* Maſt tree, Deale tree, but moſt generally Firre tree.

*The Vertues.*

The barke and dry Roſſin of the Firre tree, is in property very like unto the properties of the Pine tree, but that this is more ſharpe and more cleenſing. The cleare Turpintine or liquid Roſſin of the Firre, is hot and dry in the ſecond degree, and very cleenſing withall, yet as I ſaid not ſo fit for any inward as outward medicines, being ſomewhat too hot ſharpe and nauſious to many, and eſpecially ſeeing we have two other ſorts of Turpintine fitter for inward griefes, it is of excellent uſe in all ſalves and Balſames that are for the head, or any other greene wound or old ulcer, cleenſing very much the old filthy ſores, and helping to heale them after, and ſodering up the lips of the freſh.

## CHAP. CXVII.

### *De Reſinis.* Of Roſſins.

HAving now ſhewed you all the trees that beare gummes or Roſſins, I thinke it not amiſſe to entreate a little more largely of the Roſſins, and Gummes themſelves apart, both to ſhew you the ſeverall ſorts of them, and the ſeverall manners of drawing them forth, which I could not either well doe before, or were omitted to ſpeake of them here, and have their names muſter all in one place, but becauſe Gummes and Roſſins would be too much to handle in one Chapter: I will onely make the Roſſins my taske in this Chapter, and the Gummes in the next, and for that Roſſin is of two ſorts dry and moiſt, I will ſpeake of them in each Section, but of the dry ones in the firſt place, and of the moiſt after.

Roſſin is an oilinous ſubſtance diſſolving and melting of it ſelfe by the heate of the fire, and apt to burne with a flame, and called ῥητίνη in Greeke, and *Reſina* in Latine, the dry Roſſin is called ῥητίνη ξηρά *Reſina arida*, and ῥητίνη φρυκτή *Reſina fricta*, boyled Roſſin, that is, ſuch as from the Turpintine or liquid Roſſin is boyled with water in great kettles or cauldrons, into our ordinary yellow hard Roſſin or into blacke Roſſin, which is uſually now adayes called *Colophonye*, yet ſome ſay that *Colophonye* is the foote of the Turpintine, after the oyle is deſtilled from it, and ῥητίνη ὑγρά *Reſina liquida*, liquid Roſſin which is Turpintine.

1. *Reſinæ Cedri.* The Cedar Roſſins.

There commeth out of the great Cedar tree, a dry Roſſin of it owne accord, hardning upon the tree, which being chewed ſticketh ſo faſt to the teeth that it can hardly be pulled from it.

There is another alſo drawne from it that is liquid, and both of them called *Cedria*, but this liquid eſpecially, for that there is more ſtore of it gathered, and is of more uſe alſo, and is drawne from the tree by boring it at the young knots before the barke be rugged, and ſetting an hollow horne to the hole, that it may runne out thereat into veſſels ſet under to receive it, and is of as ſweete a ſent as the Strawberry ſaith *Lugdunenſis*, and not as *Dioſcorides* ſaith of a grievous ſent, for *Matthiolus* out of a very auncient manuſcript amendeth the word to be of a ſtrong ſent, or ſtrong ſweete ſent as *Virgil* his verſe doth intimate. *Urit odoratam nocturna in lumina Cedrum*: which may be underſtood of the wood alſo, but there is a certaine liquour called *Cedrium* by *Pliny*, and others, which

which is like our Tarre, and taken in the same manner from it, for they of *Syria* make Pitch of this Cedar, as also of the *Oxycedrus* the prickely Cedar, as we in *Europe* do of the Pine and *Teda*, that is, cut into stickes to burne this liquour commeth first from it in the burning, which is of that force and efficacy, that in *Egipt* they did besmeare the dead bodies therewith sundry times, which preserved them perpetually from putrefaction, for being of a caustick quality, it did feede upon, and consume the moisture in the carkase, and so kept it from putrefying, but divers have confounded both the *Cedria* and the *Cedrium* together, and the pitch likewise calling them promiscuously, some while *Cedria*, or *Oleum Cedrinum*, which is *Cedrelæon ex malis Cedri*, saith *Pliny*, and at other times *Cedrium*, when as properly *Cedria* is the *Lachrymacruda Cedri*, or *resina Cedri*, and the *Cedrium is*, the *Pix liquida Cedri*, and the pitch it selfe is *Pix Cedrina*, yet both the *Cedria*, and the *Cedrium* are of one operation: They in *Syria*, by *Pliny* his words in making pitch hereof, and of the Turpintine tree did use a kinde of furnace, wherein they piled their stickes, and made a fire round about the furnace, but put no fire within it, as we in *Europe* doe, in making pitch, as I shall shew you hereafter, when I come to speake of the pine and pitch trees. *Belloni* saith that of any of the Resinous trees as well as of the Cedar is made *Cedria*, which both *Matthiolus* and *Lugdunensis* doe worthily reprehend for so manifest an errour: The Vertues and properties whereof are set downe before, and neede not a repetition here againe.

2. The *Oxycedrus* or great prickly Cedar tree giveth a certaine dry Rossin or Gumme as it is called, somewhat like unto the Masticke, but that the graines are long, and of a more yellowish colour, but so dry if it be chewed betweene the teeth, that it will not be wrought into a paste like Masticke: but will be as a pouther in the mouth continually: this I take is called Gum *Iuniperi*, in the Apothecaries shoppes, and *Vernix* also, and *Sandarach* likewise, because the tree is so like unto Iuniper, and *Lugdunensis* saith that both the gum of Iuniper, and of the *Oxycedrus* are called *Vernix*. Hereof is made a most stinking Tarre, called by the *French huile de Cade*, when as they make pitch of the wood, as they do of the pine and pitch trees. This is most likely to be the sweet Cedar of the *Bermudas*.

3. *Resinæ Laricea*, The Larch tree Rossins.

The Larch tree yeeldeth likewise two sorts of Rossin, one breaking out at the chinkes of the barke on the body and elder boughes, which is cleere and white like unto white dryed Turpintine, and smelleth reasonable well, which will not be kept in drops, but will runne together into lumpes, untill in time it will grow dry and hard. It yeeldeth forth also a liquid Rossin, when the tree is bored to the heart as is before said, yeare after yeare, one or other, but not the same trees every yeare, one hole above another for eighth or tenne foote above the ground, which when they have so done on one side, they doe so to another, still closing up the hole close with a pinne or wedge, this yeeldeth saith *Pliny*, *lib.* 16. *c.* 10. a liquour of the thicknesse of thinne hony, which never groweth hard, and againe in another place he saith, The Larch tree yeeldeth forth a thinne Rossin of the colour of hony, smelling strong, notwithstanding that he had said that it burneth no more then a stone, nor yet maketh any coales. *Vitruvius* also *lib.* 24. *c.* 6. saith the Larch tree yeeldeth a liquid Rossin of the colour of the hony of *Athens*, which is good for those that have a ptisicke: but in that they say it was of the colour of hony, you must not understand the colour of our red hony, but such as that Country of *Athens* gave, which was nothing so high coloured as ours, and which I do in part beleeve, led by divers reasons, to thinke, that that liquid Rossen which floweth out of the Firre tree, being somewhat neare the colour of our hony was the Turpentine used formerly in the Apothecaries shops but as *Matthiolus* assureth us, the cleare white Turpentine that is in most use in the Apothecaries shoppes for inward medecines, and called *Venice* Turpentine (in imitation of the true Turpentine which commeth out of the Turpentine tree, as divers Liqueurs are called Ballames, in imitation of the true Ballame) is taken from the Larch tree, whose properties are declared before.

4. *De Resina Pini, & Picea.* Of the Rossins, of the Pine tree, and of the Pitch.

The Pine tree yeeldeth forth a kinde of fatty or gummy Rossin, that is of a whitish yellow colour, made up with a great deale of drosse for the most part, and but little cleane Rossin in severall parts to be seene in it, which doth quickely become dry, and to be made into pouther, smelling somewhat strong and sweete, and is our ordinary or common Francumsence that is usually burned in houses and chambers, to aire and perfume them, called also *Parressin*, and in shops *Resina pini in France Garipot*: this Rossin runneth out of the trees of it owne accord, and especially as *Matthiolus* and *Lugdunensis* say, out of the *Cermolo* or *Teda*, as being the sweetest, and falling upon the ground, is gathered from thence with what drosse it hath gathered into it in the spreading, and so put up with whatsoever sticketh to the barkes of the trees likewise, whereby it becommeth so foule as we have it, and therefore had neede to be melted and strained before it be used, and then will grow hard and fit to be used, there is a kinde of dry Rossin also gathered from the nuts or apples called *Resina Strobilina*, which *Galen* maketh the chiefest and best of all other Rossins, although *Dioscorides* maketh it the last and worst. It yeeldeth no other liquid Rossin that I can learne: but from it and the sorts thereof, before it turne into *Teda* as after, but especially then, as having most store of pitchy matter in it, is made the best pitch and most store, and is made in *Europe*, where the trees grow, somewhat after the manner of making charcoales with us: For having prepared a place for the purpose, paved in the middle, and raised up also a little, with a trench round about it, for the pitch to runne into, they pile up the stickes and cloven wood, setting them upright to a sufficient heighth and breadth, this pile or heape they cover with the branches of the tree, plashed close together, and very well limed or lomed on the outside, quite all over, that no chinke be therein, for if any happen it must be presently stopped with lome, that no flame or fume passe out thereat, for feare of loosing all, and onely one hole left below, where the fire is to be kindled, which also must be stopped up after the fire is well kindled, and that the liquour beginneth to runne into the trench, which must have severall gutters from it to be led from thence into others fit to receive the pitch as it runneth out: the Tarre and water with it runneth first out, which is kept together, and the pitch that commeth out after by it selfe, and then barrells are filled up with them severally: the thinner liquour is called *Pix liquida* in Latine, and πίσσα ὑγρὰ in Greeke, and when it is boyled againe and made harder πίσσα ξηρὰ and παλαμπίσσα *Pix arida vel sicca*, and *recocta*, but the *Pissasphaltum* is a bituminous or hard pitch, taken out of the earth, and was used to be melted with Tarre to temper it, and make it serviceable for ships. The Vertues whereof being not specified before, shall be shewed hereafter in the end of the Chapter.

5. *Resina Picea.* The pitch tree Rossin.

The pitch tree likewise thrusteth forth a whitish Rossin gathered betweene the barke and the tree, and breaking out

out into drops, so like unto *Thus* or *Olibanum*, that many did counterfeit it therewith, as *Galen* saith *lib. 2. decomp. med. secund gener. c. 2.* and *lib. 3. c. 2.* who calleth it πιτύινον φίσημα *Piceæ bulla*, and this peradventure may be that Rossin of the pitch tree, made in *Asia*, and called there *Sphagas* as *Pliny* saith, who also in another place saith hereof, that the pitch tree giveth a great deale of Rossin so like unto *Thus*, that being mingled together, they can scarse be discerned to be severall: this Rossin also is used to be mixed with the pine tree Rossin before spoken of, which is likely to be *Galen* his συνκομίση, and with them the *Resina strobilina* mixed all together: out of this tree likewise being wounded as in other trees for that purpose, is drawne forth a liquid Rossin, like unto that of the Firre tree, called by *Pliny Pix Brutia*, as I take it, which is redder then the ordinary Rossin, and peradventure may be also the *Colophony* of the ancients, which was like *Resina fricta*, and brought from *Colophony*, but more tenacious, as betweene Rossin and pitch, which I take to be that which is usually called with us now adayes *Burgony* pitch, which while it is fresh is somewhat soft in working, and sharpe in sent, but afterward growing as dry as a dry Rossin, that will easily be made into pouther. Of the wood and stickes hereof as of the pine, either together or separate is made pitch, as is before shewed.

6. *Resina Abiegna*, The Firre tree Rossin or Turpintine.

Some doe say that there is gathered from the Firre tree, a dry kinde of Rossin passing out thereof voluntarily as is before said of the pine and pitch trees, and put altogether to make our common Francumsence, which how true or false it is, I cannot either maintaine or disprove, the knowledge of many such things, although of daily use is not easily attained, by them that dwell farre from the naturall places of their growing. From this Firre tree being bored to the heart, as is done in other the like, and some say out of the pitch tree as well, issueth forth in the younger trees a cleere yellowish Turpintine or thinne Rossin, but from the elder somewhat thicker, which being put into great cauldrons is boyled with a double quantity of water, but I thinke twice double will not serve, so long even two or three dayes continually night and day, untill it become so throughly boyled and dryed, that it will not yeeld to a thrust, when it is cold, but will be hard and dry, and then is called yellow Rossin, and being molten a new is cast into great cakes, of an hundred weight a peece more or lesse, and according as the Turpintine is in clearenesse and goodnesse so will the Rossin be, and this is the ρητίνη φρύκτη of the Grecians, and *Resina fricta* of the Latines.

7. *Resina Cupressina*. The Rossin of the Cypresse tree.

There is sometimes found on this tree, a certaine kinde of dry Rossin, but so little that we have little knowledge thereof, and lesse use, *Dioscorides* and *Pliny* doe both make mention of a liquid Rossin, to be taken out of it as out of the Turpintine tree Larch tree and others.

8. From the Savine trees likewise of both sorts, in the hot Countries is taken a dry Rossin.

9. From the *Cedrus Lycia*, the Cypresse like Cedars of both sorts, is taken such like dry Rossins as from the *Oxycedrus* in small peeces falling to pouther in the chewing like unto it.

10. From the *Arbor vitæ* sometimes is taken a dry Rossin in small peeces and small quantity.

11. From the *Arbor Thurifera* is gathered the *Thus* or *Olibanum*, but what the tree is from whence it was taken we know not, nor they that have made mention of it, for some say one thing and some another, so that I dare say no more of it here, but in the next Classis.

12. Of the dry or liquid Rossins taken from the Lentiske or Masticke tree, from the *Balsamum* or Balme tree, from the *Styrax* or Storax tree, and from the Turpintine tree, I have spoken sufficiently before, saving onely that I would give you further to understand that in *Syria*, and the parts neere thereunto they make pitch of the Turpintine in the same manner as they doe of the Cedar, besides the cleere true Turpintine that is drawne forth by piersing the tree, as in other Rossin bearing trees.

*The Vertues of Rossin and Pitch.*

Rossin in generall as *Galen* saith, that is of all sorts, is hot and dry, but they differ much one from another, in being more or lesse sharpe and hot, and of thin parts: the *Strobolina*, that is, the Rossin taken from the nuts of the pines is the hottest, and that from the Turpintine tree the most temperate, the dry white Rossin of the pitch tree is hot and dry, but yet is not so drying as the *Strobolina*, although more heating: that of the Firre tree is as a meane betweene them both, even as that *Colophony*, which smelleth and is like *Thus* or *Olibanum* is temperate likewise, the moistest of them all is that other sort of the Larch tree Rossin, which is the sharper, of the stronger sent, and more bitter taste: The *huile de Cade* or stinking Tarre, comming from the *Oxycedrus* or prickely Cedar when it is burned, healeth all scabbes and itch in man or beast, and other deformityes in the skin, as the Lepry morphew and the like, and performeth in a manner whatsoever the *Cedria* it selfe can doe. The Venice Turpintine boyled to a dry Rossin, is farre better then any other ordinary boyled Rossin to stay the flux of Gonorrhea. The common Francumsence, *Parrossin*, or Rossin of the pine tree besides the uses to burne and perfume a house as is before said, it serveth in salves as a principall ingredient, to heale and fill up with flesh hollow ulcers, and to warme and comfort any cold griefe or part of the body: The Rossin of the pitch tree, called *Burgony* pitch, in being sharper and more hot, is much used for searcloathes against cold aches, and all sorts of paines and griefes proceeding of cold, and by reason of the sharpe and quicke sent, is the more piercing: The pitch it selfe is hot and dry in the second degree, yet mollefyeth hard knots tumours and swellings, it bringeth boiles and sores to supparation, and breaketh carbunckles, and blanes, disperseth and scattereth botches and emposthumes, draweth forth corruption in sores, and healeth them by causing flesh to grow up in them, and is used in many salves, both oyntments and plaisters that serve to draw and to heale: The Tarre water that commeth first out and with the Tarre, doth kill any Tetter or Ringworme being used thereon, and likewise any itch, and healeth up scabbes or scalles in the head. the Tarre it selfe is hotter then the pitch, and is used saith *Dioscorides*, against poysons, as also is good for those that have the Tissick or cough, or rotten flegme stuffing the lungs, and for hoarsenesse and tough flegme, that will not easily be expectorated: being rubbed with salt on a place that is bitten by a Serpent helpeth it, and being mixed with as much waxe it taketh away the ruggednesse of the nailes, it helpeth the hardnesse of the mother, the rifts in the fundament, the chaps on the hands or feete, it stayeth also spreading ulcers, it breaketh or dissolveth the kernels under the eares and throate, called the Kings evill, being made up into a pultis with Barley meale, and a boyes urine, and applyed warme: it is likewise dropped into the eares with a little oyle of Roses to cleanse the mattering of them: it stayeth creeping ulcers applyed with Brimstone

or

or the barke of the pine tree, or with branne: The blacking that is made of the pitch when it is burned, healeth watering eyes, and the fretting sores in the corners of them: and with it and ordinary Turpintine well mixed, is made the Printers Incke where with they print Bookes, but not our ordinary Incke now adayes, howsoever it might be in use in *Dioscorides* his time. The Turpintine that commeth out of the Firre tree is sharper and hotter then that of the Larch tree, and more nausious to be taken inwardly as I said before, and therefore more usually put into salves, and for outward remedies: The Rossin that is made thereof is neere unto the property of Pitch clensing heating drawing, and mollefying as well, and drying more then pitch: the pouther of Rossin is almost as effectuall as Amber pouther in the running of the reines, experimented by sundry Chirurgions, who have used it instead of the best sort of dryed Turpintine, which is for the same purpose, either to try conclusions or to save charges: it is used with pitch in many salves, or without it for all the purposes whereunto pitch serveth for all greene wounds to heale them, and for all old sores and ulcers to clense them, incarnate and heale them up afterwards: it may be used in fumes with Olibanum, Masticke, and other things that are burned, and the head ayred with their smokes to helpe to dry cold rheumes, catarrhes, and distillations from the head. The Rossin of the Cypresse tree is heating and binding, and serveth effectually for all the purposes that is spoken before of the nuts or leaves, or what else thereof is used: The Rossins of the small Cedars are neere the property of the prickely Cedar, although not so effectuall or violent, In the like manner whatsoever droppeth or runneth forth from the Sabine trees is sharpe and hot like the leaves, &c. of the tree: and for the *Arbor vitæ*, although there hath been sometimes a kinde of Rossin found sticking to the barke of the tree, yet it hath beene in so little quantity, that I have not learned what use any hath made of it. The other Rossins of the Balme tree, Turpintine, Lentiske and Storax trees are spoken of sufficiently in their proper Chapters, and need not a repetition here againe, of the same things there delivered: The Vertues of the *Thus* or *Olibanum*, you shall have in the next Classis with the relation thereof.

## CHAP. XCVIII.

*De Gummis arborum & herbarum earundemque succis condensatis.*
Of the Gummes of trees, and herbes, and of the dryed juyces of them.

THe Rossins of all sorts being declared in the former Chapter, there remaineth to speake of Gums issuing both out of Herbs and Trees, and the condensate juyces of plants, yet *I* must except out of this number and Chapter the gummes and dryed juyces, whose plants are not knowne to us, from whence they proceede, and that are brought of old or of later dayes, from the East or West Indies, which are of use in physicke, for I determine to handle them in the next Classis, with the forraigne drugges in the Apothecaryes shops. I have as you see here joyned the condensate juyces unto the gummes, because to them that know not their manner and nature, they seeme to be gummes, one as well as another: and that I may shew you the difference betweene a gumme and a dryed juyce, and both of them from the Rossins before spoken of, thus they are: Gummes are of two sorts, one that is of a watery or earthy substance, and will dissolve in warme or cold water, wine, or the like, and not in or with oyle, nor melt of themselves, being set to the fire, and will burne without flaming, and such are the Gummes of many trees. The other is oylious or unctuous and in part resinous, in that it cleaveth so fast to any thing toucheth it, and that will not dissolve with cold water, wine, or vinegar, but onely with warmed wine or vinegar, and will also better dissolve of themselves being set to the fire, then the other gummes will, and will give a flame in the burning, yet nothing so much as the Rossins, which as I shewed before are wholly unctuous, meltsng with the heate of fire, and burning with a flame like oyle and such like unctuous matter being set on fire: Another difference of a Rossin from a Gumme is this, that all Rossins although liquid (some sooner or later then others,) will be dryed to be made into pouther; the juyces have scarse any of them any unctuous matter in them, being onely composed of a watery and earthy substance, condensate together, which wholly dissolveth with water and burneth like earth: to begin therefore.

1. *Gummi Arabicum.* Gumme Arabecke.

Is a certaine cleare white Gumme that is brought from the parts beyond the Seas, and is taken to bē the Gumme that commeth out of the *Acacia* tree of *Egipt* by many good Authours, *Bellonius* also confirming it, who travailed through those parts, and observed it, and *Alpinus* who lived a while in *Egipt*, yet some have taken it to be the gumme of plumme trees, or of other trees growing in those parts: It is of sundry formes and colours, for some are in round hard dry peeces, of the bigneſse of a Tennis ball, or bigger, or not halfe so great or lesse, all of them rugged and not smooth on the outside, but whitish for the most part, which being broken is cleare pure, white and transparent, yet some more or lesse then others, and some are very small long peeces, and therefore called *vermiculatum*, and held for the best, being in substance like the other peeces of the same greater size, are reddish, yet cleare and transparent also, which some take to be the gumme of some other tree, because it is of such a different colour, but that is no sufficient reason to disprove it, for we see in divers others sorts of gummes, that the severall peeces doe not all hold one forme or colour, and yet are true: this dissolveth of it selfe in water, and serveth as a glew to stiffen binde, or fasten many things: the tree hereof shall bee declared the second Chapter after this, for the manner thereof, it distilleth or droppeth out of the tree in bigger or lesser peeces, as either nature list to thrust it forth, or as it is helped by cutting the barke and giving it way to issue forth, which sticking too, and not falling off or upon the ground, is so gathered and reserved.

2. *Gummi Prunorum & Cerasorum.* Plumme tree and Cherry tree Gumme.

The Gums of both these trees come forth in the same manner that is said of the former, being of severall colours each of them, that of the Plumme tree for the most part being whiter then the other, which is redder: yet both of them cleere and more clammy then the former, and vary, some of the Plumme trees being reddish, and of the Cherry trees white.

3. *Gummi*

3. *Gummi Amygdalarum & Persicorum.* Almond and Peach tree Gummes.

Both these trees likewise yeeld Gummes very like unto the Plumme and Cherry tree, that it is somewhat hard to distinguish them, but that they are somewhat whiter and a little dryer. Thus having shewed you all the Gummes of the Trees that are knowne to us, let me in the next place shew you the other sorts of Gums, taken for the most part from the rootes of Herbes and plants.

4. *Gum Tragacantha.* Gum Tragacanth.

This Gumme as I have shewed before in speaking of the plant called Goates thorne is taken from the rootes hereof as they grow, a pit being made round about the roote, which will in the greatest heate of Summer, being deepely wounded, thrust forth very slender small peeces, crooked or writhed, seldome greater then a tagges point, or ones fingers end, and most usually a great deale smaller; some very pure white, and others a little yellowish, and some more reddish, much of it gathering drosse, which sticketh fast unto either barke or stones, or earth, or the like: the gumme it selfe is sweetish in taste, and quickely relenting in water into a gelly, like made starch, and glewing things together as firme as starch or glew, in small and thin materials. The properties hereof are declared with the plant.

5. *Opopanax.* The Gumme Opopanax.

This gumme taken from *Panax*, the All heale of *Hercules* is a yellow gumme, very browne on the outside and yellow within being broken, the best is pure or sincere, that is, not mixed with stickes or drosse, but cleane gum, and in small drops, yet sticking fast together, of a sowrish sent, and somewhat strong, and being dissolved with wine or vinegar, will make it looke yellow, even as the herbe it selfe, being broken will yeeld a yellow sap or juyce in our owne Land: from the rootes chiefly and not from the stalkes is this gumme taken, in the like manner as I shewed you of the gumme tragacanth by digging a hole round about the roote, and laying boordes or tyles or the like, round about and in the bottome to keepe the gumme cleane, from earth, stones, or any other thing that might foule it, falling among it after the roote is cut in three or foure places, as some doe, or making a hole or two therein as others doe, whereunto the gumme will be drawne, and from thence flow forth: In the Classis of Vmbelliferous plants are the Vertues expressed whereunto I referre you.

6. *Galbanum.* The Gum Galbanum.

The great *Ferula* or Fennell giant of one sort, is the plant from whence this gumme is taken, and that not in every Country for that onely which groweth in *Syria*, as *Dioscorides* saith yeeldeth Galbanum, the rootes being wounded in the same manner as is before said of the *Panax*: the gumme smelleth strongest of any of the *Ferulaceous* gummes, and is if it be sincere a little yellowish, with white peeces amongst it, and divers parts of stickes or stalkes broken among it, and sometimes the seedes also, so clammy and tenacious that one can hardly touch it without cleaving to their fingers, and dissolving onely with wine or vinegar.

7. *Sagapenum.* The Gum Sagapen.

As *Syria* bringeth forth the *Ferula*, from whence *Galbanum* is taken, so is *Media* the nourse plot, as *Dioscorides* saith, where the same or another *Ferula* groweth, from whence the gumme *Sagapenum* or *Serapinum* is taken in the same manner that the former is, and doth not much differ from it, but that it is not so clammy, or gummy, but dryer, and of a redder colour, and smelleth not halfe so strong or stinking as it doth: The Vertues both of *Galbanum* and *Sagapenum*, are amply set forth under the title of *Ferula*.

8. *Gum Ammoniacum.* The Gum Ammoniacum.

This gumme likewise is taken from a *Ferula* as it is said, growing in *Cyrene* of *Africa*, so that you see the diversity of the climate, although in one and the same plant produceth diversities of gums, differing both in forme and operation: this gumme is much whiter then any of the three last mentioned, pure and sincere without any sticke or stalke in it, and with many whiter peeces among it, and not smelling any thing so much as the *Sagapenum* doth, which also being dissolved, will be whiter then any of the former. The properties of this Gum is very like unto the two last of the *Ferulous* gums, and thereunto you may referre it.

9. *Euphorbium.* The gum of the burning thorny plant.

This gum is taken from the thorny plant *Euphorbium*, as we have beene alwayes informed from others, and not from any kind of *Ferulous* plant, as *Dioscorides* saith, the forme of which plant, as it hath come from beyond the Sea unto us, even a small plant, we have here before exhibited unto you, the gum is of a browne yellowish colour, and somewhat whiter within, in almost as small graines and drops as Masticke, of a most violent burning hot piercing sent, piercing the nostrils if it be but a little stirred, but much more and allmost intollerable to him that shall beate it, and more to them that shall take it inwardly, the properties hereof are declared with the description of the plant.

10. *Sarcocolla.* Sarcocoll.

This is a small reddish and whitish gum in very small peeces and pouther, little bigger then Poppy seed, somewhat bitter in taste, and ready to provoke casting, but of no sent almost at all, *Dioscorides* saith it is taken from a tree in *Persia*, which neither he describeth, nor we have any further knowledge of, it clenseth and dryeth, it closeth up greene wounds, and stayeth catarrhes, defluxions and redness in the eyes.

11. *Gum Hederæ.* Gum of Ivy.

The gum that is gathered in the hot Countryes from the stems and greater branches of the Ivy tree is of a very darke red or browne colour, comming to us in small drops, cleaving fast together in lumpes, a little cleare, and of somewhat a strong sent, but very sharpe and burning: it killeth nits and lice, and some doe put it into a hollow tooth to helpe the ach, being mixed with things convenient for it: some use this gumme with other things, and some alone, made up with a little hony and crummes of bread into a paste, and cast it into standing pooles and ponds of fish to make them turne up their bellies and lye as dead above the water for a small time, that they may be taken, which will returne to their senses againe.

12. *Scammonium.* Scammony.

I have made a long narration hereof in the second Classis of this Work, whereunto I must referre you, and onely shew you here that the generall vote of the Writers thereof, is that the juyce hereof is taken from the rootes of the plant, ordered in the same manner that is shewed in gathering the gummes of *Panax* and *Ferula*, *&c.* but I am halfe perswaded it is otherwise, and made in another manner, because it doth not condensate into graines

or

or ſmall peeces as thoſe aforeſaid, but is made into a whole uniforme lumpe or maſſe, of a darke grayiſh colour, ſomewhat light and not ponderous, a little ſpongy alſo, or with ſome holes in it, ſomewhat cleare and not muddy or droſſie, of a ſtrange and ſtrong taſte, almoſt procuring caſting, and giving a ſhew of milke upon the moiſtening with the tongue, but not burning in the mouth or throate, for that is a ſigne of adultering: The qualities are expreſſed at large in the place before named.

13. *Aloes.* *Aloe ſuccotrine.*

The Herbe *Aloe*, or Sea Houſeleeke, I have likewiſe largely entreated of in the ſaid ſecond Claſſis before, with the whole manner of drawing out and preparing the juyce, whereunto I muſt referre you, ſo to ſave a tautologie or repetition of the ſame things againe, which were too tedious.

14. *Opium.* *Opium.*

This alſo with all that can belong thereunto, I have expreſſed in the Chapter of Poppy before, and cannot adde unto it any thing, more then is there ſet downe with the Vertues and Cautions, in as ample manner as I can.

15. *Elaterium.* *Elaterium.*

Aftër I had given you the deſcription of the wild Cowcumber, in the ſecond Claſſis before, I declared the making of the *Elaterium* of two ſorts, both greene and white, as may be ſufficiently gathered from what is there ſaid, and therefore I ſhall forbeare to ſay any more thereof in this place, referring you thereunto, where the properties are alſo expreſſed.

## CHAP. XCIX.

### *Palma.* The Date tree.

ALthough there be divers kindes of trees that goe under the name of *Palma* in Latine, whereof *Pliny* in his time mentioned three ſcore and one, and ſince his time many others not knowne to him, have beene brought to light, yet there is but one kinde of Date tree properly ſo to be called without variety, howſoever the climate where they grow, ſeeme to make a diverſity, of greatneſſe or goodneſſe one from another in the fruite, ſuch as *Theophraſtus* and *Pliny* reckon, and although againe, for want of a fitter *Engliſh* name, as the former Writers have thought, they have beene called Date trees generally: yet I would if I could avoid that improper name, and rather call them Palmes for the diſtinction of them: I will therefore in this place give you onely the deſcription of the true Date tree, and thereto adjoyne two other called *Palmitos*, which others doe account low or wilde Date trees; when in truth they have little or no rëſemblance thereunto, ſaving a little in the leaves, and ſpeake of ſuch other Palmes, as have come to our knowledge, in the next Claſſis.

1. *Palma vulgaris.* The ordinary Date tree.

The Date tree uſually growethvery great and tall, yet in ſome places nothing ſo high as in others, bare of branches unto the toppe, the barke whereof is not ſo well to be ſaid ſcaly or rugged, as knaggy, having ſhort knagges, which are the ends of the middle ribbes of the leaves, ſticking out round about the body, which give an eaſie footing like ſteps, to climbe or get up into the toppes of the trees to gather the fruite, the leaves that grow at the toppe are very long and large, made as it were of divers parts, and foulded together double; the middle rib being thicke and almoſt wooddy, but ſpongy within, which doe alwayes abide greene, and hang downewards with their ends: the flowers are encloſed in a long skinny ſheath, hanging downe from the lower branches of leaves and ſometimes higher, which opening it ſelfe at the end into two parts, ſhew forth a number of white Saffron-like ſmall flowers, hanging by ſmall threds in great bunches together; after which come the fruite, upon the ſaid threddy footeſtalkes, greene at the firſt, and reddiſh when they are ripe, with a hard firme ſmall long and round whitiſh ſtone with a furrow in the middle: ſome ſorts are ſmall, and ſome great, ſome of a ſoft ſubſtance ſome firmer and harder, ſome whitiſh, ſome yellowiſh, or reddiſh, or blackiſh, ſome round like an Apple, others long with the roundneſſe, ſome having the toppe ſoft, and ſome none at all, ſome ſo ſweete and luſhious that they will not keepe long, unleſſe they be preſſed into cakes to be kept, others will abide whole for a long time, and fit to be ſent alſo into any farre Country: yet all of them having a ſmall round hard crowne or cap at the head, which with rubbing one againſt another falleth off: the ſtones within the fruite, notwithſtanding that they are ſo ſollid and firme as a very ſtone, and can hardly be broken with an hammer, yet having a ſmall hollow place in the middle of them, with ſo ſmall a kernell therein, that it would not be thought to ſpring thereby, yet being put whole into the ground hath ſhot forth long narrow hard leaves, and have abiden in a convenient warme place divers yeares, without any great progreſſe, ſo little it liketh ſo cold a climate.

2. *Palma humilis ſive Chamæriphes vel Palmites.*

The wilde or low Date tree called the *Palmito* tree.

The *Palmito* or low or wilde Date tree groweth in divers places of *Europe*, not to be above a yard high in the ſtocke or body, ſhooting out leaves from thence very like unto the former Date tree, but much leſſer and ſhorter: this beareth a round head at the ſide of the leaves, compoſed of many foulds of skinnes, which breaking open, ſhew forth a number of white flowers, ſtanding upon ſmall thready ſtalkes: this head being cut off, before it open it ſelfe for flowers, is very delicate to eate like a Coleflower or Cabbage, and more pleaſant then either Hartichoke, Chardon, or Tartoufli be, and are ſerved to rich mens tables for a ſallate of great delight.

3. *Palma Chamærops Pliny ſive Chamæriphes ſpinoſis foliis.* The Thorny *Palmito.*

This groweth in a manner wholly like the laſt, but the leaves being made as it were of many hard plaites have many ſharpe and ſhort prickes or thornes, on the backe of them, and the ſtalkes of them likewiſe, whereby it differeth from the other, whether the heads and fruite be alike, I cannot certainely heare.

*The Place* and *Time.*

The manured Date tree groweth in all the Eaſterne Countries generally, *Galen* and *Pliny*, with others commended thoſe eſpecially above others, that grew in *Iudæa*, and in the valley of *Hiericho*: *Bellonius* ſaith, they deſerved not commendations, neither were they ripe about *Ieruſalem*, above a moneth after they had beene gathered in *Egypt*: they grow alſo in *Italy* where they are planted but beare no fruite, and in *Spaine* by the Sea ſide,

*Palma vulgaris & legitima.*
The ordinary and true Date tree.

*Palmæ spatha cum fructu & floribus.*
The blooming and fruite of the Date tree.

2. *Palma humilis sive Chamæriphes.*
The wild or low Palme, called the Palmito tree.

3. *Palma Chamarops Plinij sive Chamæriphes spinosis foliis.*
The thorny Palmito.

but the fruite is nothing so good as in *Cyprus* and the *Levant*. The other two sorts grow, the first in *Sicilia*, *Candy*, *&c.* the other in *Spaine*: they flower in *Aprill*, and are ripe in *November* or later.

*The Names.*

The Date tree is called in Greeke Φοῖνιξ *Phœnix*, in Latine *Palma*, and the fruite Δάκτυλοι καὶ φοῖνικες *Palmulæ* and *Dactyli*; the sheath or skin which encloseth the flowers, is called Ἐλάτη *Elate*, and σπάθα *Spatha*, and some thinke one kinde of Date is called *Palma Elate*: the best sort of Dates are called *Caryotæ* and *Phœnicobalanus*, which were also called *regiæ*, because they were fittest for the dyet of Kings. *Thebanes* were the leane dry Dates, that had little substance in them: the ancient Writers have set downe many things of Dates, that there is male and female, and that they both beare fruite, so that they be within the sight one of another, or else they will not beare, but I pray you account this among the rest of their fables. The second is called χαμαιρίφες by *Theophrastus*, and *Chamæriphes* in Latine by *Lobel*, *Lugdunensis*, and *Palma humilis* also by *Matthiolus*, and *Palmitee* or *Palmito* by the vulgar in *Italy*, *Spaine*, *&c.* the Greekes also call that head that is used to be eaten ἐγκέφαλον, the *Italians* and *Spaniards Cefaglioni*, The other is called by *Lugdunensis Chamærops Plinij*. The *Arabians* call the Date tree *Machla*, and *Nachal*, and the fruite *Tamar*, the *Italians Palma* the tree, and *Dattoli* the fruite, the *Spaniards Palmeira*, and *Tamarás*, and *Dattiles* the fruite, the *French Palmier*, and *Dactier*, and *Palmes*, and *Dactes*: the *Germanes Dattelbaum*, and *Dattelz*, the *Dutch Dayeboom*, and *Dayes*, and we in *English* Date tree, and Dates.

*The Vertues.*

The unripe Dates are very harsh and binding, and the ripe also while they are fresh more then when they are dry, staying womens courses, vomittings, and the laske of the belly, and stay also the bleeding and falling downe of the fundament and piles, being taken in red wine: if they be used that are dry, they helpe the hoarsenesse and roughnesse of the throate, the sharpe cough by reason of sharpe rheume falling on the breast and lungs, the decoction of them taken, alayeth the force of hot agues, and stayeth spittings of blood, the paines in the stomacke and bowels, because of a flux, and boyled in old *hydromel*, that is, mede or honyed water, and taken doth refresh the spirits: used likewise in brothes or meates they doe the like, and somewhat provoke unto enery, but being taken too often, or too liberally, they breed head ach, and a kinde of perturbation of the braine, like unto drunkennesse, and the leprosie also as it is said, the sheath out of which the flowers breake, is very astringent, and so are the leaves also in the cases aforesaid: the decoction thereof maketh the haire blacke, being often used, and stayeth fretting ulcers, and helpeth the weakenesse and paines in the backe, in the bladder, and in the bowels: the Date stones being burned and washed serveth in stead of *Spodium*, to binde and restraine the fluent humours into the eyes, and to consume the pinne and web in them, and to dry up pushes being used with Spik nard, it stayeth the falling of the haire from the eyebrowes: being mingled with wine and used, it helpeth any excressences out of the flesh, as wennes and such like, and bringeth foule ulcers to cicatrising: *Diaphœnicon*, which is the Electuary made of Dates, purgeth choller and flegme very effectually, so it be taken with good caution and advise, and that from two drammes unto sixe in white wine, or a decoction of Sene, as shall be thought fit, and is conveniently given in compound and long agues, and in those diseases that are bred of raw humours, as in the chollicke the paines of the backe and mother. The head of the Dates, or Date braines, is very pleasant and savoury to the taste, and is much used where they grow to be eaten with a little Pepper and salt: of the leaves of the *Palmito* they use to make Broomes to sweepe the house, which last a long time; of them likewise they make Mats, and Baskets.

## CHAP. C.

*Acacia sive Spina Ægyptia.* The *Egiptian* thorne or binding Beane tree.

*Dioscorides* hath made mention of two sorts of *Acacia*, the one of *Egipt*, and the other of *Cappadocia*, and *Pontus*: *Theophrastus* also speaketh of two sorts, blacke and white: that of *Egipt* is reasonable well knowne, but of that sort of *Pontus*, there is some controversie among Writers, some taking one bush to be it, and others denying it to be it, the differences of *Theophrastus* sorts are onely expressed in the wood, as it is likely, the white to rot quickely, and the blacke to be long lasting and of very good use to many purposes, *Dioscorides* having described them. I shall therefore here shew you them, and with them adjoyne another sort of *Acacia* brought out of the West Indies, mentioned by *Aldinus* in his *Farnesian* garden.

1. *Acacia sive Spina Ægyptia vera.* The true *Acacia*, that is *Egiptian* thorne or binding Beane tree.

The *Egiptian* Thorne groweth in some places to be a great tree, and rather crooked then straight or rising high, covered with a blackish barke, spreading abroad great armes and branches, full of sharpe thornes, with many winged leaves set on both sides of them, that is, with foure winges of leaves on a side, made of sundry small ones, set opposite on a middle rib, without any odde one at the end, although it be so expressed, *Bellonius* saith that he counted 350. of those small leaves, that were upon the whole branch, and yet all of them might but cover his thumbe: the flowers grow among the branches, like flockes of wooll, of a whitish yellow colour, where after come somewhat large and thicke huskes, like unto the *Lupine* or flat beane cods, blacke when they are ripe, and bunched forth against the places where the seedes lye, in some three or foure, and in some more, each as bigge as a small wild Beane, round, and of a grayish or ash-colour, almost shining: the tree abideth alwayes with greene leaves thereon, and yeeldeth of it owne accord a white gumme in small curled peeces like great wormes, and greater round peeces if it be wounded.

2. *Acacia Americana Farnescena.* The West Indian *Acacia* or binding Beane tree.

This Indian *Acacia* groweth like unto the Hasell nut tree saith *Aldinus*, with many stemmes if they be not cut away that it may rise to be a tree, with slender and flexible branches, covered with a smooth thinne barke, like the Hasell, the young ones being of a greenish ash-colour on the North side, but that next the Sunne more pale, spotted with white spots: the leaves hereon are variable, which although they be all winged, yet some have but foure leaves on a side, some have five, sixe, seven, or eight, with an odde one at the end, each paire set opposite, and

1. *Acacia vera sive Spina Ægyptiaca.*
The Egiptian Thorne or binding beane tree.

2. *Acacia Americana Farnesiana.*
The VVest Indian Acacia or binding beane tree.

like unto Lentilles, closing or foulding themselves upon the Sunne setting, and opening againe after the rising, having at the foote of every stalke two long thornes set, reddish at the first, and white after: the first flowers come forth in the beginning of *Iuly*, after some few leaves have shot forth from the old wood, but not in any plenty, yet bring the fruite to ripenesse after: but in the beginning of *September* more plentifully, yet without any fruite following them: these flowers at the first are greene, and like a small Strawberry, growing yellowish after, and whitish within two or thee dayes like unto a pill, or small round ball, consisting of a flocky or woolly substance, many of them set together, and have many small threds in the middle with yellow tips, of a very sweete sent, like unto the sent of Wall flowers, which hold their sent long after they are dry: from the middle of the flower come forth divers cods, yet sometimes but one or two, or three, and sometimes more, greene at the first, and blacke when they are ripe, like crooked round hornes, while they are greene, of a very harsh and binding taste, but growing ripe they are lesse astringent and the huske more sharpe, and then doe somewhat resemble the cods of *Lupines*, but a little crooked, being halfe a foote long, and about an inch thicke, somewhat round and bunched out, where the seedes lye, which huske is very tough when it is dry, wherein are divers hard blacke seedes, like unto those of the sweete Beane or *Carob* tree, thrust thicke together without order, the wood hereof is hard and whitish, but blackest at the heart, without either sent or taste: this doth in many things agree with the former, but the greatest difference is in the huskes with seede, this having many, and the other but three or foure at the most, The like hereunto *Lobel* mentioneth in his *Adversaria, pag.*409. that he saw with Master *Morgan* Queene *Elizabeths* Apothecary.

3. *Acacia secunda sive altera Dioscoridis.* The true second *Acacia* of *Dioscorides.*

This bush hath an upright stemme three cubits high or more, covered with a smooth sad greene barke, the wood being soft and easie to breake, and not very thicke of long thornes, the leaves are small, standing three together upon the branches, the flowers are small and yellow, whose succeeding seede seated in small huskes, are round, hard, flat and yellowish, somewhat like to Broome seed: This shrub seemeth very like to the *Aspalathus secundus* of *Dioscorides*, but differeth notably therefrom, in that the *Aspalathus* is thicker set with greater whiter and sharper thornes, with fewer and smaller leaves, flowers, and seede vessels, and the wood thereof is hard, and not easie to be broken.

*The Place* and *Time.*

The first groweth in *Arabia* plentifully in many places, and mount *Sinai*, and in *Egipt* also, and flowreth and beareth fruite twice a yeare, whereby we may well say, it beareth ever greene leaves: the other came out of the West Indies, *Aldinus* saith his came from Saint *Domingo*, but from whence that which Master *Morgan* Queene *Elizabeth* her Apothecary had long agoe, as *Lobel* setteth it downe in *Adversaria*, is not knowne whether it came from thence or no, the seedes springing in Cardinall *Farnesius* his Garden in *Rome* as it is set forth by the said

said *Aldinus* in his description of some rare Indian plants growing therein, and flowred and bore fruite as it is expressed in the description. The last in *Candy* and *Græcia*, as *Pona* saith.

*The Names.*

*Dioscorides* calleth it in Greeke *ἀκακία*, and *Acacia* in Latine also, and *Theophrastus ἄκανθα* & *Spina* simply without any other adjective, whereof he maketh two sorts as I said, *alba* and *nigra*, the white being weake and quickely rotting, the blacke being strong, fit to build houses, and ships, &c. *Alpinus* maketh them to be *mas* and *fœmina*, the male fuller of thornes and without fruite, the female having fewer and gentler thornes, and those within the branches, bearing plentifully. *Pliny* also calleth it *Spina Ægyptia* in some places, distinguishing it from the *Arabica*, and in others confoundeth it with the *Spina Arabica*, which are much differing, this being a Thistle as it is shewed among them, and that a Thorny tree: Some have thought that the *Acanthus baccifera* of *Virgill*, mentioned in the second of his *Georgickes*, in these words *Quid tibi odorato referam sudantia ligno Balsamaque & baccas semper frondentis Acanthi*, should be this tree, as *Servius Grammaticus*, and *Christoferus Landius* both of them Commenters upon *Virgill* say; but without true judgement as *Guilandinus* noteth it, who would referre it to the *Acanthus Ægyptia* of *Athanæus*; *Marantha* referreth it to that kinde of *Ebenus*, whereof *Pliny*, *lib.* 12. *c.* 5. maketh mention, but there is as little certainety in this, as in the former, for concerning this it is not specified by *Pliny*, that it either beareth berryes, or yet abideth ever greene, and for the former, this *Acacia* beareth not berryes, such as no doubt *Virgill* meant: but it is most probable he intended, the *Pyracantha*, that we most usually so call, for *Pliny* so called it also, and *Spina* as some have it, or *Spinus lib.* 15. *c.* 24. where he saith *Baccæ Aquifolij & Spinæ sine succo.* But now concerning the juyce of *Acacia*, the true and not the substitute should be used in those two famous compositions, *Mithridatum*, and *Theriaca Andromachi*, and there is no doubt, but our Apothecaries might have sufficient of the true to use, and expunge the substitute, if they would bespeake the true to be brought, being made there in *Egipt*, where the tree groweth of the greene cods, which *Acacia* will be reddish, such as I have seene with Master *Boxe* the Drugist, which is the best: or else made of the cods which will be blacke, for if the Apothecaries would themselves extract the juyce out of them, and condensate it *secundum artem*, they might have enough of the cods brought them for that use. *Lobel* mentioning the *Acacia*, in the place before recited, saith that *Sequinus Martinellus*, a Physitian and Apothecary of *Venice* sent his brother *Albertus*, divers sackes full of these cods, whereof some was reduced into juyce, and some of the seedes were planted and grew into trees, as *Lobel* there mentioneth. The hardned juyce likewise is called *Acacia*: some have called it *Spina Christi*, thinking that Christs Crowne was made of the boughes of this tree, but it is more probable it was made of the *Paliurus*, it is now generally through all *Turkie* called *Acacia*, and so likewise of the *Egiptians*, as *Alpinus* saith, and *Sant* also: *Rauwolfius* saith that the *Arabians* at *Haleppo*, call it *Scamuth*, and *Schacke*. The Gumme that commeth out of the tree, whether voluntary or by incision is called *Gummi Arabicum*, although divers doe doubt that the gumme that beareth that name, is not the gum of this tree but some other, yet it is assured to be right by *Alpinus*, *Bellonius*, and others, yet there is a small sort of gumme likewise brought to us, of the like whiteneſſe and clearenesse with the other, but is *Vermiculosum*, in small crooked peeces like unto short thicke wormes. The second is called by *Aldinus Acacia Indica Farnesiana*, who hath made a long comparison betweene it and the former *Egiptian*. The last is remembred by *Pona* in his *Italian Baldus*.

3. *Acacia secunda seu altera Dioscoridis.*
The true *Acacia* of *Dioscorides*.

*The Vertues.*

The hardned juyce extracted by decoction out of the cods of this tree, and called *Acacia* as I said, with the gumme thereof are the most especiall parts thereof we know are used, yet the juyce of the leaves and the rest worketh like them, but farre weaker: the juyce being used in all such diseases as neede binding, cooling, and strengthning, and staying vomitting, used inwardly or outwardly: and is available in the defluxions of hot humours into the eyes to stay them, and the abundance of womens courses, with the falling downe of the pallate, and of the fundament, and the flux of the belly, and the spitting of blood, and all bleedings, it resisteth also creeping ulcers, Saint *Anthonies* fire in the beginning, and helpeth the ulcers of the mouth, and secret parts, kibes, and chilblanes, and the growing of flesh over the nailes, and to fasten loose teeth, and the fluxe of humours to the joynts, that weakeneth them, and when they have beene bruised or put out of their place: the same also made into a decoction and the haire rubbed or washed with it, maketh it blacke, and is much commended to those that have the gout: the gum hath a property of thickening, and cooling, and to represse and coole the heate, and sharpenesse of humours, and to binde or close up the open passages of the skinne, and keepeth the places from blistering

that are burnt with fire, being used with the white of an egge: it serveth also for Limmers to fasten their colours for Dyers also in their Dying, for inke, and many other externall civill uses.

## CHAP. CI.

*Arbores aliæ spinosæ & siliquosæ Indicæ.* Certaine other thorny Indian trees, bearing cods.

I Have certaine Indian Thorny trees to bring to your consideration that beare cods, whereof some have beene entitled *Acacia*, but I call *Pseudoacacia*: Another very like thereunto, called by our Colony in *Virginia*, *Locus*: whereunto I have adjoyned a third which hath growne with us, and a fourth called the Corall tree, and because they are differing much from those in the former Chapter, I have thought it fit to make a Chapter of them peculiarly.

1. *Pseudoacacia Americana Robini.* *Robinus* his false *Acacia* of *America*.

Because *Jacobus Cornutus* in his Booke of *Canada* plants, hath entituled this tree *Acacia*, although with little judgement; I have given it a place with another *Virginia* like it, but not with the true ones as is most fit. The body (saith he) is smooth, covered with a comely smooth blackish barke, without any thornes thereon at all, spreading the armes and branches very farre, which while they are young are pithy within, beset with many cruell sharpe thornes, flat at the bottome, ending in a small sharpe point: the leaves are many set on both sides of a middle ribbe, from seven or eight, to tenne or more on a side, and an odde one at the end, each leafe foulding it selfe double every evening upon Sunne setting, and opening againe upon the rising: the flowers are white, somewhat like Pease blossomes, or those of *Cytisus* Tree Trefoile, many set together on a stalke, standing upright and not hanging downe, shewing themselves in *August*, after which follow hard rough prickly pods, but I and others had from *Robinus* such smooth pods as is expressed in the figure, under the other, in each whereof was enclosed one or two small browne Lentill-like seedes. By this description you may plainely see how much it differeth both from the true *Acacia* of *Dioscorides*, and the other *American* of *Aldinus*, having nothing therein but thornes answerable; and therefore in my judgement it doth better agree with some *Spartum spinosum*, then *Acacia*, but that it is a tree.

2. *Arbor siliquosa Virginensis spinosa, Locus nostratibus dicta.* The *Virginian* Locus tree.

A very like tree hereunto hath beene sent and brought us out of *Virginia*, growing to be a very great tree, and of an exceeding height with Master *Tradescant*, whose body is covered with a smooth barke, the young branches being greene, and set with somewhat sharpe prickles at every joynt, where the winged leaves come forth,

1. *Pseudoacacia Americana Robini.* *Robinus* his false *Acacia* of *America*.

2. *Arbor siliquosa Virginensis spinosa Locus nostratibus dicta.* The *Virginia* Locus tree.

which

3. *Arbor spinosa Indica muricatis siliquis.* The prickly codded Indian tree.

4. *Siliquosa & spinosa trifolium Indica arbor dicta.* The Indian Corall tree.

which are set in the like manner with the other, with an odde one at the end, and some not, but are somewhat shorter and rounder: we have not seene the tree to beare any flowers with us as yet nor fruite, but the cods that came to us, were small, long, and somewhat flat like unto the pods of *Laburnum* Beane trefoile, but longer thinner and blacker, containing small grayish shining flat and round seede.

3. *Arbor spinosa Indica muricatis siliquis.* The prickely codded Indian tree.

The seede taken out of the prickly huskes of a tree that was brought from the West Indies, was sowne by Master *George Willmer* at *Stratford Bow*, and rose up that yeare to be three or foure foote high, branched forth on all sides, and set with small sharpe crooked thornes, both on the maine stemme and branches, having sundry winged leaves set on them, very much resembling the last *Virginian* Locus. I can give you no further relation hereof, in that the plant perished in the next Winter after the first springing, for want of such due keeping as was fit for such tender plants, that come out from warme Countries: The figure of the prickely huske or pod, you may see set on the side of the figure, with the grayish pease taken thereout also, which was as hard as a stone, with a white kernell within them, yet not sinking in the water.

4. *Siliquosa & spinosa trifolia Indica Coral arbor dicta.* The Indian Corall tree.

*Clusius* first, and since him *Baptista Ferrarius* by the sight thereof, growing both at *Rome* and in *Spaine*, hath enlarged the description of this tree, which I will contract into one, and tell it you thus. It riseth up with many stemmes, whose younger barke is smooth and greene, the elder paler and more rugged, spreading fairely with branches, armed with small crooked whitish thornes, and with faire broad fresh greene and almost round leaves, like unto those of *Arbor Iudæ*, *Iudas* tree, but that they end in a point, whose footestalkes also as *Clusius* hath expressed, have the like crooked thornes on them, which leaves are three alwayes set together, the two lowest opposite on short footestalkes, the end one on a longer: the flowers are Pease fashion, or like those of *Phaseolus* the Kidney Beane, of an orient red colour like Corall, of which colour also are the Beanes or fruite in pods, like unto other *Phaseoli*: it is very tender to keepe, not abiding the least cold aire, for as *Clusius* setteth it downe *Signior de Tonar*, the chiefest Physitian of *Sevill* in *Spaine* in his time, having two trees hereof growing, which by one Winters oversharpenesse had them both spoyled therewith. I have not altered the name hereof, whereby it is generally knowne, but if I might adopt one, as I thinke more fitting thereunto, I would entitle it *Phaseolus arboreus spinosus Indicus flore corallino.*

*The Place* and *Time.*

All these foure sorts came from the severall part of *America*, but we cannot tell you where distinctly, for the two last, but the first it is likely came from *Canada*, the *French* plantation, and the second from *Virginia*: The flowring and seeding is likely to be at the time of other trees at the Spring and Fall.

The

*The Names,*

The first as I said *Conutus* calleth *Acacia Americana*, such a glorious title doth he set upon so unbeseeming a Plant, I have put *Robinus* name thereto, because it is generally called *Acacia Robini*. The second is called Locus by our Nation resident in *Virginia*, The third came to us without name, but it is likely to be the *Bonduch Indiano*, of *Pona* in his *Italian Baldus*, which he referreth to *Clusius* his first strange fruite in the 30. Chapter of his second Booke of Exotickes, as also to the first in the 15. Chapter of his third Booke. The fourth was first set forth by *Clusius* in his Appendix to his History of Plants, sent him by *Tovar* out of *Spaine*, and enlargeth the description thereof, especially of the flowers in his second Appendix: *Baptista Ferrarius* in his *Flora*, or *de florum cultura* setteth it forth bravely, but without flowers; as having not as then shewed them.

*The Vertues.*

None of these have beene tryed to what griefe or disease they are a remedy, but onely the third, which if it be *Pona* his *Bonduch*, as I am certainely perswaded it is, then he saith, these particulars are attributed unto it to ennoble it: The *Egiptians* in *Alexandria* account it the guardian of their children, in tying it about their neckes, to defend them from all evill chances; to preserve one from the venome of the Scorpion, to helpe the Megrime by taking some of the pouther into the nose, and the torture or writhing of the mouth, is availeable also against the falling sickenesse, by taking the quantity of two Pepper cornes at a time: the quantity of a Cich Pease taken in Wine helpeth the chollicke and the quartaine ague, is a remedy for any poyson, which saith he I have not yet tryed: the fruite saith he was sent from *Constantinople*, and these Vertues affirmed to be in it, and there esteeme it of great worth.

## CHAP. CII.

*Gossipium.* The Cotton tree or plant.

I Have foure sorts of Cotton trees or plants to shew you that have come to our knowledge, or that we can be assured of, although *Bauhinus* saith there is one with a white seede, which is his first, whereof I never heard or read, and is likely to be mistaken, for all those Authours that he doth cite for it, doe all intend the annuall Cotton, whose seed is in lumpes, and blacke.

1. *Gossipium arboreum.* The tree of fine Cotton.

This Cotton riseth up with a wooddy stemme, to be nine or ten cubits high, spreading wooddy branches, and many broad greene leaves on them, parted on the edges into three or five divisions, somewhat like a Vine leafe, but softer and whiter, at the ends of the smaller sprigges come forth, the flowers, two or three at a place, but

1. *Gossipium arboreum.*
The tree of fine Cotton.

2. *Gossipium frutescens animum.*
The bush or Lumpe. Cotton.

each

3. *Gossipium Indicum spinosum.* Thorny Indian Cotton.

4. *Gossipium Iavanense longifolium.* The long leafed Cotton tree of *Iava*.

each upon a slender footestalke, set in a broad huske of two leaves, very much jagged at the toppes, and containing therein a large yellowish flower, somewhat like a bell flower, broad above and small at the bottome, parted to the bottome into five very thinne leaves, with a stiffe reddish middle pointell, compassed with five or sixe yellow threds, which is thrust of by the fruite, rising under it, and growing to bee a small round head or ball, covered with a hard skinne, which opening when it is ripe, sheweth forth a lumpe of pure white wooll, having divers small blackish seede of the bignesse of Pepper cornes, but not so round, lying dispersedly through the lumpe, and singly but one in a place, with a sweet whitish kernell within them, the roote dispersetb under ground and abideth, not perishing nor losing the branches as the next doth.

2. *Gossipium frutescens annum.* The bush of lumpe Cotton.

This Cotton is yearely sowne, even in the warmest Countryes of *Asia minor*, and within foure monethes or little more is gathered againe from the sowing, shooting an upright stemme, nothing so wooddy or great as the former, but brancheth forth divers wayes, set with large and broad soft leaves, like the former, and parted alike, the flowers also stand in the like manner, and yellow, with purple bottomes, with huskes of fine leaves under them, after which commeth the fruite like it, but set in a shorter, smaller, thicker, and harder rough blackish huske parted into three cells, with whitish hard shining skinny or wooddy partitions on the inside, containing each of them a round ball of fine white Cotton, with a lumpe or bunch of greater blacke seedes by the halfe, in the middle, sticking close together in two rowes, with white sweete kernells within them: The roote as I said is annuall, and perishing as soone as it hath perfected the seede.

3. *Gossipium Indicum spinosum.* Thorny Indian Cotton.

This kinde of Cotton hath a stemme about three cubits high, set with small prickes, and having many faire broad leaves set thereon upon long footestalkes, divided into seven parts, somewhat like those of *Stravisacre*, the flowers are like to Bell flowers with five corners, the Cotton is very fine, and the seedes are somewhat like the Thorny Mallow.

4. *Gossipium Iavanense longifolum.* The long leafed Cotton of *Iava*.

This as *Clusius* relateth it from *Franciscus Rodorigues*, native of *Beugala*, groweth on a great high tree, with many farre spread armes and boughes, and stored with long and narrow leaves, neerer resembling Rosemary then Willow leaves, but that they are much longer, whose fruite was like a long pod of sixe inches long, and five in compasse, growing great from the stalke upwards, opening and ending in five pointed parts, whose skinny barke was of an ash colour, and rugged, but full of most pure white soft wooll, and divers blacke round seedes within, not involved with the Cotton like the rest, but growing by themselves upon fine long wooddy partitions, extended all the length of the cod: the wooll or Cotton was shorter then of the other, and not fit to be spunne into thred to make cloath, for the Natives use it not to that purpose, but put it to another use, namely to stuffe cushions and the like, being softer then any wooll, cotton, or feathers.

*The*

*The Place* and *Time.*

The first groweth not naturally in all the lesser *Asia*, but as *Alpinus* and *Bellonius* and others say in the greater *Asia*, and *India*, and *Brassill* also, and *America*, and brought into *Egipt* and other Christian Countries, but as a rarity: The second hath for many yeares beene planted in the severall Countries of *Asia minor*, *Phrigia*, *Cilicia*, and other the parts thereabouts, and in *Apulia* also, and in many of the Isles in the *Mediterranean* Sea, and sowne not untill the end of *Aprill*, and gathered againe in the end of *August* or in *September*, the third came out of *India* likewise, and the last from about *Bantam* in *Iava*, the former sort ripening the fruite somewhat more early then the other.

*The Names.*

It is called in Greeke ξύλον and γοσσίπιον, and so likewise in Latine, *Xylum* and *Gossipium*, and of *Serapio Coto*, and *Bombax*, as it is so also called in the Apothecaries shoppes: Some doe thinke and that not without good ground of reason; that the *Byssus* of the Auncients, is this first Cotton, from whence was made the *Byssina tela*, the fine white Callico cloath, that commeth out of the East Indies: All Authours call them in generall *Xylum* or *Gossipium*, and the first *Gossipium arboreum* by *Alpinus*, and by the *Egiptians* as he saith, *Gotne msegiar*, it is more likely that *Bellonius* meant this tree by his *Arbor lanifera*, then that of *Clusius* in his Exotickes brought out of *Iava* and fittest for cushions, and *Gossipium perenne arboreum sive Asiaticum*, and *Brasilianum* by others. The second is called *Gossipium herba*, to distinguish it from the former, *Bauhinus* calleth it *Gossipium frutescens semine albo*, for sure he can meane no other sort, citing those Authours that he doth, who all I think say it is black. The third is extant only in *Pona* his *Italian Baldus* by the name of *Bombage Indiano*, that is *Gossipium Indicum*. *Bauhinus* calleth it *Gossipium arboreum caule spinoso*, and saith the seede is in lumpes like the ordinary sort, when as *Pona* himselfe saith it is like the seede of *Subdarifa*, that is, the thorny Mallow, and pictureth the seede like thereunto, at the side of the figure, and is not like the lumpe sort. The last *Clusius* mentioneth in the foure teenth Chapter of his first Booke of Exotickes, calling it *Arbor lanifera peregrina*. *Bauhinus* that he might say somewhat, referreth it to the *Cyla* of *Oviedus*, and questioneth whether it be not *Bellonius* his *Lanigera arbor*, calling it himselfe *Gossipium Iavanense salicis folio*. The *Arabian Serapio* as you heard, calleth it *Coto*, and *Bombax*, and others *Algodon*, as the *Spaniards* doe; the *Italians Bombagia*, the *French Cotone*, the *Germans Baumwool*, the *Dutch* and we Cotton, and Cotton wooll.

*The Vertues.*

The kernells of the seedes is used to lenefie the hoarsenesse of the throate, and to helpe those that are shortwinded, to open the passages, and for those that have sharpe distillations on their lungs, and for coughes, to make the flegme the easier to be expectorated, and encreaseth sperme also: it is used also in gripings, and gnawings of the stomacke, yea though they come by poyson, and are good also in all hot agues, the Cotton it selfe is hot and dry, and being burned stancheth bleedings in wounds wonderfully: the oyle drawne out of the seed doth smooth the skin, and taketh away spots and blemishes therein.

---

## CHAP. CIII.

*Arbor Iudæ. Iudas* tree.

OF the *Iudas* tree there hath beene observed two sorts, one with crimson, and the other with white flowers.

1. *Arbor Iudæ flore purpureo.*

*Iudas* tree with crimson flowers.

This *Iudas* tree riseth up sometimes to be high, and of a good size, and sometimes to be but as an hedge bush, spreading armes and branches, covered with a blackish red barke, the leaves that come forth upon the young reddish branches one at a place, are large and round, greater, but thinner then the leaves of *Asarabacca*, of a whitish greene colour on the upper side, and grayish underneath, falling away in Autumne: the flowers grow not at the ends of the branches, but at the joynts, and sometimes out of the very body, many standing together upon a long footestalke, of fashion somewhat like unto Pease blossomes, of an excellent deepe crimson colour, after which follow sundry long flat and large thinne cods, of a reddish browne colour, with flat blackish browne hard seede within them: the roote groweth deepe and spreadeth farre.

*Virginiana.* Of this sort there is one growing in *Virginia*, not differing from it in any thing, that I can as yet perceive.

2. *Arbor Iudæ flore albo.*

*Iudas* tree with white flowers.

This other groweth as great as the former, but with a whiter barke, and the branches greene, the leaves and flowers are like for forme, but of a white colour, and the cods after them, nothing so browne as in the former, and the seed likewise paler.

*Arbor Iudæ. Iudas* tree.

The

*The Place* and *Time.*

These kindes grow in *Narbone* and *Provence* in *France*, and in *Spaine* and *Italy* in many places: the flowers generally appeare before the leaves breake forth, yet bringeth not the cods to maturity in our Country, yet we have had them growne large and very reddish, but contained not any ripe seed within them.

*The Names.*

It is not certainely knowne that either *Dioscorides* or *Theophrastus*, have made mention of this tree in all their Workes, for although some have taken it to be that *Colytæa* of *Theophrastus*, which he mentioneth in his third Booke and foureteenth Chapter, but unto this he attributeth a leafe like unto Willow, which this is utterly unlike, others againe, that is, those of *Mompelier* as *Clusius* saith, unto that *Colytæa* of *Ida*, that *Theophrastus* mentioneth in the seventeenth Chapter of the said third Booke, whereunto he attributeth the leafe of the larger leafed Bay tree, but larger, rounder, and somewhat like the Elme leafe, yet somewhat long with all, greene above and whitish underneath, and whereunto saith *Clusius*, he in the foureteenth Chapter of the said third Booke attributeth cods, the descriptions of both which saith he, being contracted into one, agree well unto this *Arbor Indæ*: but by *Clusius* his leave, this cannot hang together; for although they in both those Chapters, that is, the 14. and 17. are called *Colytæa*; yet they are plainely distinguished by *Theophrastus* both in their leaves, the one like a Willow, the other like a Bay leafe, but rounder; and also in their fruite, that with the Willow leafe hath cods saith *Theophrastus* like unto Pulses: but that with broad Bay leaves, hath a *Chachrys* or *Amentum* as *Gaza* translateth it, and is said to be without flower or fruite, and besides hath yellow rootes: so that you may see plainely both those cannot be contracted to make one plant, their leaves being declared to be so divers: Some therefore would referre this tree unto the *Cercis Theophrasti* mentioned in two places, the one in the said foureteenth Chapter of his third Booke, where he saith it is like the white Poplar tree, both in greatnesse and whitenesse of branches, with the leafe of Ivy, &c. which *Clusius* thinketh is but an ample description of the third kinde of Poplar called *Lybica* the Aspen tree (which *Gaza* translated *Alpina*) the other place is in the first Booke and 18. Chapter, where he reckoneth *Cercis* to be one of those trees that beareth fruite or seedes in cods, as *Colutea* of *Lipara* doth, so that you see in this *Clusius* was also mistaken, as *Matthiolus* was also before him: but indeed this description of *Cercis* commeth neerest unto this *Arbor Indæ*, of any other tree that hath beene likened unto it. Some have called this tree in Latine *Fabago*, from the likenesse of the cods unto Beane cods, and some to be *Laburnum* or some kinde thereof; but the most currant name is *Arbor Indæ*, yet *Clusius* calleth it *Siliqua sylvestris*, not as he saith, because it doth agree with the *Siliqua* of the Auncients, but because the *Spaniards* called it *Algarovo Loco* which is as much as *Siliqua fatua*, and those of *Castile Arbold amor*, the *French* call it *Guainier* because the cods are like knive sheathes, we have no other *English* name to call it by, then *Indas* tree, untill some other can impose a more apt for it. It is judged by many that *Matthiolus* his first *Acacia*, in his former editions, was but a counterfeit figure of this *Arbor Indæ*, whereunto he caused thornes to be put to make it seeme the more probable.

*The Vertues.*

There is no remembrance of any Physicall property appropriate hereunto either by ancient or moderne Writers, nor hath any later experience found out any: but from *Virginia*, we heare they account the flowers to be an excellent sallat ingredient.

## CHAP. CIV.

### *Vitis.* The Vine.

THere is a wondrous great variety of Vines that are manured, as I have shewed else where in my former Booke, some there are that grow wild, which shall be declared in this Chapter, with a recitall of some of the choyfest of the other.

1. *Vitis Vinifera.* The manured Vine.

The manured Vine in places where it hath stood long, hath a great stemme as bigge as ones arme sleeve and all, spreading without end or measure if it be suffered, many slender weake branches, that must be sustained from falling downe, the young being red, and the old of a darke colour, with a pith in the middle, at the sundry joynts whereof, grow severall large broad greene leaves, cut into five divisions and dented also about the edges, at the joynts likewise against the leaves come forth long twining tendrels, clasping or winding about whatsoever it may take hold of: at the bottomes of the leaves, come forth clusters of small greenish yellow flowers, and after them berries, thicke set together in bunches of severall formes, greatnesse, colour and taste, in some the clusters are close, and others are more open, and some being round, others more long, and some tending to a square: some likewise are very small, as the Curran Grape, others great, and some a meane betweene both: some againe are white, others blacke, or blewish, or red, or parti-coloured, and for tastes, they are so variable that I cannot describe them, both sweete according to the severall climates they grow in, and sower or harsh, or mixt, more or lesse pleasant one then another, within which there are usually one two or three kernels: They that keepe their Vines in the best manner doe keepe them low, and cut them often, both Winter and Summer, whereby they grow the better, and take up lesse roome, bringing their Grapes both fairer and sweeter.

2. *Vitis laciniatis foliis.* The Parsely Vine or Grape with thin cut leaves.

This also groweth as other Vines doe, the difference chiefely consisting in the leaves, which are very much incised or cut into many parts, even almost to the middle, and dented, the Grapes which are white and great, are like unto the white Muscadine Grape, and of as good a rellish, bearing great bunches, and ripening with the middle sort of Grapes.

3. *Labrusca sive Vitis sylvestris Europea.* The wild Vine of *Europe.*

The wild Vine in regard it is naturall, and therefore neglected, lyeth for the most part on the ground, and thereby is made lesse fruitefull, unlesse it meete with some hedge or tree, whereon it may clime, and then spreadeth as the

1. *Vitis Vinifera.*
The manured Vine.

*Vitis Laciniatis folijs.*
The Partly Vine or Grape.

the manurēd, being both in branches, leavēs, and tendrels, likē unto thē manured Vine, as also in blossomes, but beareth either little or no fruite, or seldome comming to ripenesse, and what it doth is small and blacke, and no way comparable unto any of the manured Vines, being rather binding and sowre then sweete.

4. *Vitis sylvestris Virginiana.* The wild Vine of *Virginia.*

This one sort of the Vines of *Virginia*, like all other wild sorts runneth on the ground, and taketh hold of whatsoever it meeteth with, being in all things like the former wild sorts, but that the Grapes are small and white, and with little sappe or juyce in them, and the kernell twice as bigge as others. There is another sort that hath bigger blew Grapes, and sowrer in taste. A third they call the Foxe Grape, and hath a more rugged barke, a very broad leafe, without any division almost but dented, and the Grape is white, but smelleth and tasteth like unto a Foxe.

*Alba.*
*Cærulea.*
*Vulpina.*

5. *Vitis sylvestris trifolia Canadensis.* The wild Vine of *Canada.*

This wilde Vine of *Canada* groweth like unto other the wilde Vines of those parts with slender reddish branches, climing where it can get whereon; but the leaves on them being little more then halfe so large as the manured Vine, hath onely three partitions in every leafe, but each cut in deepe, even to the long smooth stalke, whereon they stand, making them seeme as three leaves, which are of a darke greene colour, and somewhat thicke also; the fruite is like the other wild sorts, having more skinne and kernell then substance or juyce.

*The Chiefest Grapes are these:*

The *Damasco* white Grape, which is the true *Uvæ Zibebæ*, that the Apothecaries should use in sundry of their compositions.

The Muscadine Grape both white and red.

The Frontignacke or Muske Grape.

The party coloured Grape.

The Raisin of the Sun Grape.

The Curran Grape is the small blew Currans that the Grocērs sell, and have no kernells, whereof there is another sort that beareth red berries, almost as small but not so sweet, or rather a little tarter.

The small earely blacke Grape.

The blacke Grape of *Orleance.*

There is a Grape without stones growing in sundry places, as by the River *Soreke* nēerē *Ascalon* in *Palestina*, giving a red wine, as also in divers places of *Arabia*, *&c.* and in the *Maderas*, *&c.*

There is reported also to be one that beareth greene leaves continually, yet yeeldeth fruite but at the time that others doe.

There is said likewise to be some that beare twise in a yearē, and some oftener, having both ripe and greenē fruite together at one time upon the tree.

*The*

*The Place* and *Time.*

The manured kindes are planted every where, and according to the soile and climate is both the rellish and strength of every sort, for the Vine that groweth in the *Canary* Islands, is the same with that at *Malaga* and *Sheris*, and yet the one still excelleth the other in strength and sweetnesse. The other wild sorts are all expressed in their titles: the first wild sort in sundry places of *Europe*, both *Italy*, *France* and *Germany*. The wild sorts flower somewhat later then the tame or manured, and therefore what fruite they beare, must likewise be later ripe then others.

*The Names.*

The manured Vine is called in Greeke ἄμπελος οἰνοφόρος and ἥμερος, and in Latine *Vitis Vinifera*, and *sativa* or *culta*: the wilde is called ἄλπελος ἀγεία, and in Latine *Vitis sylvestris*: *Vitis a vino, vel quia invitetur ad uvas pariendas dicitur*, but there is another *Vitis sylvestris* of the *Grecians*, that is the *Clematis urens* of the Latines by some, and the *Amaradulcis* by others, when as this is called *Labrusca*, to cause it to be knowne asunder: the juyce of the unripe Grapes of the manured Vine, or rather of the Grapes of the wilde Vine, which come not to ripenesse are called ὀμφάκιον in Greeke *Omphacium*, and *Agresta* in Latine, in *English* Varjuyce: The Grapes when they are dryed in the Sunne are called *Unæ passæ*, and *Passule solis* Rasins: the juyce or liquour pressed out of the ripe Grapes is called *Vinum* wine: the kernels are called γιγάρτα *acini*, the dregs or setling of the Wine, are called *Vini fæces*, Wine lees while they are moist, but being dryed is called *Tartarum*, *Tartar* or *Argoll*, the destilled Wine is called *Spiritus vini*, or *Aqua vitæ*, the spirit of Wine or *Aqua vita*. In the wild Vine the flowers are called οἰνάνθη, and *Oenanthe*, that is *Vini flos* in Latine, which was of much use in former times, but now is wholly neglected. The *Arabians* call the Vine *Harin*, *Karin* or *Karni*, the *Italians Vite viniferera*, the *Spaniards Vid* and *Parra*. The *French Vigne*, the *Germanes Weiureb*, the *Dutch Wijn gaert oft Wijnstacke*.

*The Vertues.*

The Vine hath in it divers differing and contrary properties, some cold, some hot, some sweete, some sower, some milde and some sharpe, and some moistening, and others drying: for the leaves and young branches are cooling and binding, and good to be put into lotions for sore mouthes, or other parts, and in drinkes against feavers: being bruised, and with Barley meale applyed to the temples easeth the head ache comming by heate; and applyed to the stomacke, easeth the inflammations; and heat thereof: the juyce of them being drunke stayeth the laske, castings, spittings of blood, and womens immoderate longings. The ashes of the burnt branches, or pressing, made into a lye and drunke, is very effectuall for the stone and gravell in the kidneyes: being mixed with a little vinegar, it consumeth the warts of the fundament, and the inflammation thereof being bathed therewith, it doth marvellously ease the paines, and taketh away the swelling. The said lye of Vine ashes, is good to wash places out of joynt, or burnt with fire, and used with Rue and vinegar, is good for the swelling of the spleene: and used with wine, it helpeth Saint *Anthonies* fire: the said lye also helpeth frettings and gallings in any place: the ashes made up with *axungia*, is good against hard tumours, clenseth fistulacs, and hollow ulcers, and healeth them up afterwards, helpeth the paines and shrinking of the sinewes, and being mixed with oyle easeth those places that are bruised by falls or otherwise, and cureth the bitings of Scorpions, and dogges: used with vinegar and niter, it wasteth away Wens and other excressences in the flesh. The water that droppeth from the Vine, when it is cut out of due time, being drunke helpeth to expell and wash downe the gravell and stone in the kidneys. The Gum that issueth out of it selfe sticking to the barke, being drunke in wine doth the same, (but that we seldome see any such in our country, and therefore may safely use the water in the stead thereof) and being bathed on the skinne taketh away scabbes, tetters, the morphew, and the leprous scurfe, if the places be first washed with niter: The said Gumme or the water that droppeth from the greene branches, when they are burned, being used with a little oyle taketh away haires and warts. The fresh Grapes being eaten, doe breede a little windinesse (which is incident unto all sorts of raw fruite) but stirre up the appetite, and are pleasant to the stomacke, helping to stay spittings of blood, but affect the head and the bladder: and are forbidden in agues: being hung up and dryed a little, or made into Raisins, they doe helpe to loosen the belly, especially if they be taken without the kernells, which are more drying and binding, to be taken in pouther of themselves then any other part of the Vine: Those which are called Rasins of the Sunne are the best for this purpose with us, and for any other use in physicke: and herewith are made Tisane drinkes, to helpe coughes, hoarsenesse of the throate, shortnesse of winde, toughnesse of flegme, causing it the more easily to be expectorate, and doe lenefie sharpe and nauseous humours, that offend the mouth of the stomacke: they serve likewise to open the obstructions of the liver, spleene and bladder, and taken by themselves they nourish much, by reason of their thicke sweete and temperate substance, whereby also they stay not long nor prutrifie in the stomacke. The small Raisins or Currans are very nourishing likewise, and somewhat opening the belly, especially being stewed with some other things conducing thereunto, as with a decoction of Sema, Rubarbe, and other such like things, according as occasion shall neede: The *Damasco* Raisins have a little tartnesse in them, whereby they are most gratefull to the stomacke, and excelleth the Raisins of the Sunne for all the purposes aforesaid. The juyce of the Grape is of two sorts, that is, made of unripe Grapes which is called Varjuyce, or of the ripe Grapes called Wine: The Varjuyce is a fine tart liquour fit to be used in brothes, meates, or sawses, to sharpen the stomacke, to get an appetite, and to refresh and quicken fainting spirits: Of this juyce is made a syrupe of especiall use in the like causes: the Wine is of so many sundry sorts, as not onely the Grapes, but the severall climates and soyles wherein they grow are. The weake Wines are very rheumaticke, and clense much: the strong wines are very heady, and enflame the blood very much; those of a middle temper are most proper for our bodyes (who use not willingly or ordinarily, to allay or temper our wine with water, unlesse the Vintner doe it without our knowledge or consent) and most wholesome for our health, and most in use for Physicke, both to boyle in drinkes, and to serve as the *Vehiculum*, to extract the Vertues of whatsoever shall be steeped in it, And is distributed into many parts, for of it is made both *Sapa* and *Defrutum*, in *English* Cute, that is to say, boyled wine, and both made of *Mustum*, new Wine, the later boyled to the halfe, the former to the third part. Then there is *Lora* which is a small kind of wine, like our small beere, by putting water to the pressings, and pressing them over againe, but because we have no use of such with us, I forbeare to speake further of it, *Acetum*, Vinegar, that is, sowre wine, which is as the other *ingenij non naturæ opus*, as *Pliny* speaketh of the former, for it is made by setting in the Sunne, which exha-

*Sarmenta et folia.* The branches and leaves.

*Cineres clavellatæ & eorum liximium.* Vine ashes and the lye of them.

*Lora.* Small VVine.

ling the purer ſpirits, and by the heate cauſeth the other to grow acide, and is of great uſe, both in health and ſickeneſſe, both in meate and medicine: but now adayes we have ſuch a baſtardizing, and falſification thereof, that we ſcarſe can get any right to uſe. The *Sapa* and *Defrutum* differing but onely in the manner of boyling, I may comprehend them both under *Cute*, and was deviſed to ſerve inſtead of hony, as *Pliny* ſaith, it helpeth the cough and ſhortneſſe of breath, and to expectorate tough flegme from the cheſt and lunges, it alſo eaſily paſſeth through the belly, and maketh it ſoluble. Vinegar contrariwiſe is cooling and drying, as the *Cute* is heating and moiſtening, and therefore ſerveth to correct the heate in feavers, and to reſiſt putrefaction, it cutteth tough flegme, that is hard baked, and not eaſily brought up and ſpit forth: it is ſharpe and penetrating, and very uſefull in ſcabbes, itches, tetters, ringwormes, and fretting and creeping ulcers, to correct their malignity, and extirpate their corroding quality, but is offenſive to the ſinewes, by its pierſing and drying property, cauſing them to ſhrinke. But the deſtilled vinegar is of a more fiery and penetrating quality, which it gaineth by the deſtillation thereof, the manner and order in this being quite differing from the deſtilling of Wine, wherein the pureſt and ſtrongeſt ſpirits doe firſt riſe and come forth, when as in vinegar almoſt two third parts are taken from it, which are the weakeſt, before the laſt and ſtrongeſt riſeth, but not the laſt which is the *Empyreuma*, and ſerveth even as the vinegar it ſelfe doth, but with more force, and as the *Vehiculum*, wherein the tincture and ſpirits of ſimple medicines are reſerved: But to ſpeake of Wine, from whence all theſe are made and derived, is to enter upon a little ſea of matter: for to ſhew you all the ſeverall colours, ſents, ſtrength, ages, and taſtes of ſimple wines, were too tedious and needleſſe alſo, and ſo is it likewiſe to ſhew you all the ſorts of compound or artificiall wines which are as infinite as the herbes, rootes, ſeedes, or other parts of them are, and take their names from the ſeverall ingredients that compound them, as for example Wormewood wine, Eyebright wine, Scammoniate wine or wine of *Squilles & ſic in infinitum*, as I may ſo ſay, each whereof hath the property of that herbe, roote, &c. that was put into it, while it was Muſt, that ſo they might worke together, but ſimple Wine being not made with us, theſe artificiall Wines are not in uſe with us, yet might be paralleld almoſt, if the things were put into our new Ale, or Beere, to worke in them, as wee uſe to doe with out dyet Beere. Yet other ſorts of compounded Wines might be made for ſundry phyſicall uſes, after the manner of our Hipocras wine, which is according to the ſpices put thereinto, cordiall and comfortable, &c Metheglin is a *Welſh* (ſtrange) drinke, not made of Wine, and therefore I would not reckon it among theſe Wines, being fit for ſome ſtout *Welſh* ſtomackes that affect it. The receipts of many whereof are extant in *Lobels* Appendix to his *Adverſaria*, whereunto I referre you. I will therefore touch onely the particuler properties of wine it ſelfe, both as it is medicinable and nouriſhing, for taken moderately, and by them that are of a middle age, or well ſtept in yeares, or are of a cold and dry diſpoſition, and (not very young, and ſo their blood too hot for to abide Wine) it encreaſeth blood and nouriſheth much: it procureth an appetite, and helpeth to digeſt being taken at meate, it provoketh urine and driveth forth raw humours thereby, ſtrengtheneth the vitall ſpirits, and procureth a good colour in thoſe that want it, or are macilent, drawing to a conſumption, ſo as it be not accompanyed with a fever, it expelleth feares, cares, and heavineſſe, and breedeth alacrity, mirth, and bodily pleaſure, and by the moiſt warme vapours, cauſeth quiet reſt and ſleepe, both to the ſound and ſicke that lacke it; it likewiſe comforteth and warmeth all the cold infirmities of the ſtomacke, liver, ſpleene, and wombe, and helpeth windy ſwellings in the body, and generall evill diſpoſitions thereof, the greene ſickeneſſe, and the dropſie, and the over travelled, over wearyed body and minde, it is alſo the remedy againſt Hemlocke, Coriander, Poppy, and Opium, Wolfebane, Muſhromes; and Mandrake, or whatſoever cold poyſon or dangerous herbe, or roote is taken; Theſe be the effects of the moderate drinking of Wine: when as on the contrary ſide, the exceſſe thereof breedeth a diſtraction in the ſenſes, the Appoplexie, and Lethargy or drowſie evill, the trembling of the joynts, the palſie, and the dropſie, but is uſed to heale up old ulcers, and ſores, no other moiſture being admitted in the cure. The ſpirit of Wine and *aqua vitæ*, were of ſo neere affinity in former times one unto another, that there was no more difference betweene them then betweene the ſtronger and the milder Wine, for *Aqua vitæ* being made wholly of Wine, with the addition of ſpices made the ſpirits to be the ſtronger, and the wine ſimply without ſpices to be the milder; but now there being not one droppe of Wine in the *Aqua vitæ*, is wholly deſtilled from the tilts or dregges of Ale or Beere, being their low Wines as it is called, and after diſtilled againe with a few Anneſeedes, or as ſome doe with a little Ginny Pepper, to make it the ſtronger without any other ſpice, commeth farre ſhort of thoſe auncient receites for the making of that which was good and whoſeſome: to tell you therefore the effect of our *Aqua vitæ*, were not to tell any part of the nature or quality of wine, but of Barley and Hoppes, which make Ale and Beere, I will therefore ſhew you the properties of the ſpirit of Wine, which if you will transferre to *Aqua vitæ* you may, but to farre weaker effects: for hereby ſhall you know the goodneſſe and ſtrength, by ſetting it on fire, with a paper lighted, the pure ſpirits burning fiercely, and will allmoſt be wholly conſumed: the other burning but little, and leaving an inſipide and much watery part behind it: the purer therefore that it is, the ſtronger it is, and the leſſer of it to be taken at a time, and that not of it ſelfe, but in ſome Wine or other liquour, for feare of inflaming the blood and ſpirits, and chiefly upon ſymptomes and paſſions of the heart: and then taken with reſpect and good conſideration, it worketh much more effectually then the Wine it ſelfe doth, to all the purpoſes aforeſaid, in comforting and nouriſhing the naturall heate in elder perſons, giveth ſtrength and quickeneſſe to the ſences, and nerves, repaireth memory, and the cold and moiſt diſeaſes of the braine, helpeth the fainting and trembling of the heart, warmeth a cold and moiſt ſtomacke, helpeth digeſtion, expelleth winde from the ſides and belly, and all cold poyſons: being outwardly applyed to the temples, it eaſeth the paines in the head, and cold deſtillations, and the toothach, being gargled a little, and cicatriſeth all ſores, yet reſpect muſt be had, that it be not given where any feaver is, or where the diſeaſe proceedeth of heate, or is acceſſary thereunto, for feare of hardning the liver and ſpleene, and making chollericke perſons the more enflamed: Theſe ſpirits of Wine, as well as the Wine it ſelfe, ſerves as a *Vehiculum* or menſtrue, to draw out the tincture of divers things. And now laſtly to ſpeake of the Lees of Wine, which being hardned is called *Tartarum*, *Tartar* or *Argoll*, and that which is taken from the whiteſt Wines is accounted the principall beſt for any medicine: but the red ſort ſerveth Gold ſmiths and others, to polliſh their ſilver, and Dyers in ſetting their dyes: the beſt white *Tartar* is either given of it ſelfe ſimply being made into pouther and taken, the quantity of a dramme at a time in ſome convenient drinke or broth, for ſome time together in dropſies or evill diſpoſitions of the body, to expell both by urine and ſiege, thoſe wheyiſh

*Sapa* Cute

*Acotum* Vinegar.

wheyish watery humours thereof, and applyed to womens brests that are over full of milke, doth dry them up, but the *Cremor Tartari* which is the purer part thereof, and especially if it be made as cleare as Cristall, (the highest worke of art in that kinde) doth worke more safely and more effectually then the *Crude Tartar* can doe: but this *Tartar* that is calcined untill it be white, hath then put of all purging quallity, and hath gained a causticke burning property, that will corrhode and eate away scabbed nailes and warts, and soone be brought into a salt, and will also soone be resolved into an oyle or liquour, if it be either laid upon a stone, or hung up in a linnen bagge, in a moist seller to be received as it droppeth downe, and is the most admirable *opifex* in Alchimy that ever was knowne, and not to be paralleld with any other thing, that I know: but to shew the operation of it in severall medicines by precipitation or otherwise, is not for this Worke, it must be sought out of those professed Authours of the *Spagyricke* Art, to whom I must referre you: There is another kinde of oyle of *Tartar*, of a farre milder temper, and is more like unto a cleare water, which is very effectuall to clense the skinne from all manner of spots, scarres, morphew, or discolourings whatsoever, and maketh it smooth and amiable, and where there is cause to apply it, will helpe to bring on haire on the places decayed. The wild Vines are in property no lesse cooling, but more binding then the branches of the manured, staying the laske and spitting of blood, provoking urine, and pleasing to an hot stomacke, or that loatheth meat: the leaves hereof are as good for lotions, as of the other for sores in the mouth, the privy parts and the fundament; the ashes of the branches are likewise used to cleare the eyesight of filmes, and what else may offend them, to clense sores and ulcers, and to take away the over growing skinnes of the nailes of the hands or toes. *Labrusca.* The wild Vine.

## CHAP. CV.

### *Berberis.* The Barbery bush or tree.

THe Barberry bush shooteth forth many slender stemmes or stalkes from the roote, sometimes to a great heighth, covered with a smooth whitish rinde or barke, and yellow next the Wood, which is white easie to breake, and pithy in the middle, set full of sharpe small white thornes, and three at every leafe allmost, which are somewhat small and long, finely dented about the edges, and of a fresh greene colour: the flowers come forth at the joynts with the leaves, many standing on a long cluster, yellow while they are fresh, which turne into small long and round berryes, hanging downe in long bunches, upon a small stalke white at the first, but very red when they are through ripe, of a sharpe sowre taste, able to set their teeth on edge that shall eate them, the roote is yellow and spreading.

There is another sort, whose berryes are thrice so bigge as the former, not differing in any other thing. *Fructu majore.*

There is another also, whose berryes for the most part are without any stones or kernels in them, or but here and there some. *Absque arillis.*

*Berberis.* The Barberry bush or tree.

*The Place* and *Time,*

It groweth in many of the woods in *Austria. Hungaria*, and in *France* also, the blossomes come forth in *May*, and the fruite is ripe in *September*, and *October.*

*The Names.*

It hath formerly beene held by very good and learned Authours, that this bush is the *Oxyacantha* of *Dioscorides*, and hath continued to this day, especially among the Apothecaries, yet *Cordus* accounted it an errour, and therefore would rather call it the *Oxyacanthos* of *Galen*, then the *Oxycantha* of *Dioscorides*, and so doth *Camerarius* also, but we have shewed elsewhere what the true *Oxyacantha* of *Dioscorides* is, even the *Pyracantha* which hath ever greene leaves, and red friable berryes, neither of which can agree with this Barbary bush. Others againe have taken it to be the *Spina appendix Pliny*, but *Clusius* hath shewed the unlikelinesse of that opinion. *Matthiolus* and *Cesalpinus* call it *Crespinus*, because the vulgar *Italians* doe call it *Crespino*, and some thereafter in Latine *Uva crespina*, which some attribute to the Gooseberry, but many others doe call it *Berberis*, and so the generall vote goeth now adayes. The *French* call it *Espine vinette*, the *Germanes Erbsel*, *Sawracke*, and *Versing* the *Dutch Sawerboom*, and we in *English* Barberryes.

*The Vertues.*

The leaves of Barberries make a fine tart sawse like unto those of Sorrell, and serve to coole and refresh a fainting hot stomacke and liver, and repressing sowre belchings of choller, and is therefore good for aguish people: but the fruite is much more cooling and binding, quenching thirst, and restrayning chollericke and pestilentiall vapours, and is of very good use in either

of the agues of that nature, if the conserve or the depurate juyce, or the syrupe thereof be taken with the syrupe of Violets: the said juyce also or the berryes themselves preserved, is often used for those that loath their meate, to procure an appetite, and represse the force of choller, rising from the liver thereinto, and that which passeth into the bowells procuring sharpe laskes: it helpeth likewise to stay womens immoderate courses, and if it be taken with a little Southernwood water, and sugar, it killeth the wormes in the body: it is good also for those that spit blood, and to fasten loose teeth, strengthen the gummes, and coole the inflammations of the palate and throat, and stayeth rheumes and destillations upon those parts: it helpeth likewise to dry up moist ulcers, and to soder up greene wounds: the said depurate juyce called wine of Barberyes, serveth to dissolve many things chymically: the inner yellow barke of the body, branches or roote is with good successe given to those that have the yellow jaundise being boyled and drunke: *Clusius* setteth downe a secret that he had of a friend, which is, that if the yellow barke were laid in steepe in white wine for the space of three houres, and afterwards drunke, it would purge one very wonderfully.

## CHAP. CVI.

### *Uva crispa sive Grossularia.* Gooseberryes.

THere are sundry sorts of Gooseberryes, chiefly varying in the fruite, some being larger or smaller then others, some red some greene or yellow, some blew, some round, some long and some smooth, and some hairy or prickely, which although I have shewed them elsewhere, yet it shall not be amisse, to remember them here againe.

1. *Grossularia vulgaris.* The common Gooseberry.

The common Gooseberry bush seldome riseth up to the height of a man, with a stemme as big as ones thumbe, or more, at the lower part, covered with a smooth darke coloured barke, cleere of thornes thereon, and so likewise for the most part on the elder branches, or with a few onely, but the younger are whitish, armed with very sharpe crooked thornes, which no bodies hand can well avoid that toucheth them, whereon grow small cornered greene leaves, cut in on the sides, but broad at the bottome next the stalke: the flowers are small, and grow at each of the leaves, one or two together, of a purplish greene colour, hollow and turning up the brims a little: after which follow the berryes, bearing the flowers on their heads, and are of three sorts, that is small, or great that are round, or that are a little longer then round, greene before they are ripe, and with a thicker skinne then the other, but of a greenish yellow colour when they are ripe, striped in divers places, cleere and almost transparent,

*pecies res.*

1. *Uva crispa sive Grossularia sylvestris.* The common Gooseberry.

2, 3. *Grossularia rubra & caerulea.* Red and blew Gooseberryes.

with

with small blackish seede lying within the pulpe, which is of a pleasant winy taste, acceptable to the stomacke, and without offence, although one doe eate many of them: the longer berry hath the thicker skinne, and the worser taste.

2. *Gossularia rubra.* Red Gooseberryes.

The red Gooseberry is of two or three sorts; one hath slenderer stemmes and fewer thornes on the younger white branches, which bend downe more then the former: the leaves are made after the same manner, but a little larger, the flowers and berries are like the other, but are of a darke brownish red colour, almost blacke when they are through ripe, of a fullsome sweetish taste, and never beare many in a yeare, which make them the lesse regarded: Another sort is like the former in growing with little difference: onely the berries are smaller, redder, and of a pretty tart taste, and sweet withall: A third sort groweth very like the ordinary sort of yellow, both in heighth, branch, and leafe, the berries are as large as the largest sise of the other, and of a very fine red colour, untill they be suffered to hang long on the bushes, which then are of a darkish red colour, very pleasant in taste. 1. 2. 3.

3. *Gossularia cerulea.* The blew Gooseberry.

The blew Gooseberry riseth up to be a small bush, having broader and redder leaves at the first shooting out, then the second red Gooseberry, the berryes are more sparingly set on the branches also, and for bignesse neere unto the small red Gooseberry, but lesser, and somewhat sweete, and of a blewish colour like a Damson, before the colour be wiped off.

4. *Gossularia viridis hirsuta.* The hairy or prickely greene Gooseberry.

This greene Gooseberry is very like unto the ordinary Gooseberry, in stemme and branches, but not furnished with such sharpe prickles as it, the younger branches also have smaller greene leaves: the flowers are alike, and so are the berryes; of a middle size, but greene when they are through ripe, with a shew of small haires or prickes on them, which yet are as harmelesse as if there were none, but of a more pleasing relish then any of the other: the seede hereof hath produced bushes bearing smooth berries, with few or no haires on them.

*The Place* and *Time.*

The ordinary sorts grow usually in the hedges, in sundry places of *France*, but I thinke rather planted there for defence onely, rather then that they are naturall to the Country, for even there as well as here, they are planted in Gardens and Orchards also: all the other sorts likewise are kept in Gardens: they all flower very earely in the Spring, presently after the leaves begin to come forth, and the berries are ripe from the middle of *Iuly* to the end of *August*, or as the yeare proveth.

*The Names,*

It cannot be certainely knowne that any of these fruites were knowne to any of the ancient Greeke or Latine writers, for although some have referred some of them unto the ἴσος or ὄισος *Isos*, or *Oesos* of *Theophrastus*, whereof he saith one hath a white flower and fruite, and another both blacke, yet he remembreth no thornes in it, as that hath, which so curious a Writer would not have omitted, and therefore is not likely to be this: some againe would have it to be *Vitis precia* of *Pliny*, but that cannot be, because he numbreth it among the other sorts of Vines, that beare wine as one of them: *Gesner in hortis* taketh it to be the *Ceanothus spina* of *Theophrastus*, but *Anguillara* rather judgeth his *Ceanothos* to be a kinde of Thistle, whereof we have entreated among the Thistles: it is called *Uva crispa* by divers, and *Uva crispina*, because the leaves seeme to be crispt or curld, and *Gossularia* by others, because they are like *Grossos* small greene Figges, and by some also *Uva marina*, but I know not upon what cause. The *Italians* call it *Uva spina*, the *Spaniards Uva crespe*, and *Espina*, the *French Groselles*, the *Germanes Kruss beer*, and *Kruselbeer*, the *Dutch Stekelbesien Knoselen*, and *Groesbesien*, and we in *English* Gooseberries, but in some places Feaberries, and Wineberries.

*The Vertues.*

The greene and unripe fruite of the ordinary sorts are somewhat sharpe and tart, and serve to rellish brothes for the sicke (as neede requireth,) as well as the sound to stirre up a fainting or decaying appetite, or overcome with chollericke humours, but otherwise yeeld small nourishment to the body, and that but cold and crude, for they doe a little helpe to binde the belly and stay fluxes of blood in man or woman, and stay their longings; yet they are not to be tollerated to cold or windy stomackes, least by breeding more winde they bring the chollicke, and griping paines in the belly: the juyce of the berries or of the leaves, is helpefull to coole and restraine hot swellings and chollericke inflammations, called Saint *Anthonies* fire: the ripe fruite is more pleasant, and more desired for the sweetenesse to be eaten at pleasure, then for any proper or speciall effect for any disease, but by reason of their good and sweete rellish, and moist lubricity, they easily descend out of the stomacke without any offence at all.

---

## CHAP. CVII.

*Ribes fructu rubro, albo, nigro.* Red, white, and blacke Currans.

THe stemme or stocke of the red Curran bush, hath a very thinne brownish outer barke, and greenish underneath, and of the bignesse of a good great staffe, wholly without thornes on any branch, whereon grow large cornered blackish greene leaves cut in on the edges into five parts somewhat like a Vine leafe, but a great deale lesse, the flowers come forth at the joynts of the leaves, many together on a long stalke, hanging downe about a fingers length, of an herby colour, after which follow round berries, greene at the first, and of a cleere red colour when they are ripe, of a little pleasant and tart taste withall, wherein lye small seed: the roote is wooddy, and spreadeth diversly.

There is another sort hereof, whose berries are twise as bigge as the former, and are of a better rellish. *Fructu rubro majore.*

The white Curran bush hath a taller straighter stemme, a whiter barke, smaller leaves, and such like berries upon long stalkes, and of the same sise and bignesse with the first or most ordinary, but of a shining transparent *Ribes albo*

1. *Ribes fructu rubro majore.* The greater red Currans.

2. *Ribes fructu albo.* White Currans.

whiteneſſe almoſt like Pearles, the ſeed within them being plainely to be deſcerned as they hang on the buſhes, and of a more pleaſant winy taſte, much more acceptable then the former. And is called *Gozel* as I am informed, in ſome places of *Kent*.

The blacke Curran riſeth higher then the laſt, more plentifully ſtored with branches round about, and more pliant alſo, the younger covered with a paler, and the elder with a browner barke: the leaves are ſomewhat like the former but ſmaller, and often with fewer cuts or deviſions therein, the flowers alſo are alike, but of a greeniſh purple colour, which turne into ſmall blacke berries like the former: both leaves and fruite have a kinde of ſtrong evill ſent, but yet are wholeſome, although not ſo pleaſant as any of the former, and eaten by many.

3. *Ribes fructu nigro.* blacke Currans.

*The Place* and *Time.*

All theſe ſorts have beene found growing naturally wild, ſome in *Savoy*, and *Switzerland*, as *Geſner* ſaith, and ſome in *Auſtria* as *Cluſius* ſaith he obſerved: the white ſort is not knowne, or at leaſt recorded by few, but kept in Gardens as the more rare ſort and laſt knowne to us. They flower and fructifie at the ſame time with Gooſeberries but abide longer on the buſhes before they fall or are withered.

*The Names.*

The name of *Ribes* and *Ribeſius frutex* is generally given to theſe plants for ſome likeneſſe, not onely in the berries, but much more in the properties to the *Ribes* of *Serapio*, which as he ſaith hath reddiſh greene tendrels large round greene leaves and berries, whoſe taſte is ſweete with ſome tartneſſe, and are cold and dry in the ſecond degree: This is the deſcription of *Serapio* his *Ribes*, and although all doe generally conſent it is not that of *Serapio*, as not having tendrels nor large round leaves, yet is it generally received in the ſtead thereof, onely *Dodonæus* would frame it into the ſame mould, but I doubt his skill is too weake, and his allegations too much wreſted or too ſelfe conceited. Some have thought this to be more anſwerable unto *Theophraſtus* his *Iſos* becauſe this hath no thornes as the Gooſeberries have as *Lobel* doth alſo. But *Bellonius* in his Booke *de coniferis arboribus*, and *Rauwolfius* doe both ſay they found the *Ribes Arabum* on the mount *Libanus*. *Bellonius* deſcribeth it with ſixe or ſeven leaves of a Docke, but greater and rounder, riſing from the roote, and with red berries hanging downe in cluſters, comming out from the middle of a leafe, like as the *Ruſcus*, and *Laurus Alexandrina* doe. *Rauwolfius* ſaith

ſaith, he found it onely with two large round leaves like unto the *Petaſites*, from whoſe ſtalkes a ſowre juyce is preſſed that is pleaſant, and uſed of the richer ſort, whereof becauſe we have no further knowledge, we here leave them. *Geſner* calleth this *Ceanothus levis*: moſt doe account it a kinde of *Groſſularia*, and therefore call it *Groſſularia rubro*, and *Groſſularia ultramarina*. *Cluſius* only and *Beſler* in *horto Eyſtetenſi*, make mention of the white *Ribes*, and *Bauhinus* who calleth it *Groſſularia hortenſis margaritis ſimilis*: The blacke ſort is generally called *Ribes fructu nigro*, yet *Geſner in horto* ſheweth that ſome would make it to be a ſort of *Amomum*, and therefore called *Amomum falſum* or *Pſeudoamomum*, and ſome *Pipirella* as *Lugdunenſis* ſaith. The *Italians* call it *Vnetta roſſa*, the *French Groiſelles doutremer*, the *Germans St. Johans trenblin* and *Sant Iohans beerlin*, and *Keozbeer*, as *Geſner* ſaith, the *Dutch Beſiekens over zee*, and we Red Currans, the white *Ribes* as I am given to underſtand, is called *Gozell* in ſome parts of *Kent*.

*The Vertues.*

The red and white Currans are good to allay the heate and ſainting of the ſtomacke, to quench thirſt, and to provoke an appetite, and therefore are ſafely permitted in hot and ſharpe agues, for it tempereth the heat of the liver and blood, and the ſharpeneſſe of choller, and reſiſteth putrefaction: it taketh away likewiſe the loathing of meate, and the weakeneſſe of the ſtomacke by much caſting, and is good for thoſe that have any looſeneſſe of the belly: *Geſner* ſaith that the *Swiſſers* about *Berne* where it naturally groweth, uſe it for the cough. The blacke Currans are uſed in ſawſes and ſo are the leaves alſo by many, who are well pleaſed with the taſte and ſent of them, although ſome doe miſlike them for both.

EXOTI

# EXOTICÆ, ET PEREGRINÆ PLANTÆ.

# STRANGE AND OVT-LANDISH PLANTES.

## CLASSIS VLTIMA.

## *THE LAST TRIBE.*

### CHAP. I.

*Agallochum sive Lignum,* Aloës.

ENTRING now into my last quarter, so to consummate this revolution, I must use another manner of Method, then formerly I have done in the precedent Tribes; for intending to shew you as well those Out-landish Plants, that are called spices and drogues in our Apothecaries shoppes, as other fruites and strange trees, growing in the East or West Indies, I would first perfect the more usuall Physical part of them in an Alphabeticall order and with them insert a few other, the more principall things, although not plants, or taken from them that are for the most part in our shops used in medicines, shewing the place and names of them all in a continued stile, and not in fractions, as in the foregoing parts.

*Lignum Aloes,* or the wood of the Aloe tree.

Αγαλλοχον ἢ Ξυλοαλὸη *Agallochum* and *Xyloaloe* in Greeke, is called also *Agallochum sive Lignum Aloes* in Latine, and so in *English*, or the wood of the Aloe tree, is a drogue rare to be had, and of much worth: but (as it is with many other things that come out of the East Indies unto us) of small knowledge what it is, and where and how it groweth. For but that *Garcias ab Orta* saith, that the tree is like unto an Ollive tree, and sometimes greater, and that he had the branches of the tree brought him to see, but neither flower nor fruite, the places being very dangerous by the haunt of Tigers therein, we should not know what forme it bore; none of the Ancients either *Greekes* or *Arabians*, having set downe any thing thereof, although they have all mentioned it, and the choyce of the best, with the Vertues: onely *Serapio* in the 197. Chapter of his Booke of Simples, saith it beareth small berries like unto Pepper, but red: yet *Garcias* maketh some doubt thereof, as he doth of sundry other his relations in that Chapter. For although *Serapio* in that place reckoneth up divers sorts, and *Ruellius* speaketh of foure; yet *Garcias* saith, he knew but one true sort of *Lignum Aloes*, which grew in India, and that the other sorts that were so called, were but sweete woods assimulating it, but were not the true and right wood, which the *Arabians* call *Agalugin* and *Hnud*, and they of *Surrat* and *Decan*, *Vd*, as it is likely from the *Arabians Haud*, which word with them properly signifieth but *Lignum* wood, and κατ' ἐξοχὴν, *præstantissimum*; but they of *Malacca* and *Sumatra* where the true groweth, call it *Garro*, and the best

*Agallochum sive Lignum Aloes.*
*Lignum Aloes*, or the wood of the Aloe tree.

Calambac

*Calambac*: yet as *Garcias* saith, that that sort of sweet wood that commeth from *Comorin*, and *Zeilan*, and there called *Aguila brava*, that is to say, *Lignum Aloes sylvestre*, is not true *Lignum Aloes*, which true sort as all the Auncient Authours doe set it downe, is a blackish wood in peeces, some accounting the greater peeces to be the better, but yet somewhat discoloured with veines, (some Authours saying it is so weighty and heavy, that it will sinke and not swimme being put into water: but others doe not allow of that note, saying that the best that is will swimme) and full of an oyleous substance, of a fine sweete and aromaticke sent, which it will sweat forth, when it is burned: Now to come to our later times and shew you, that for many yeares together (as many other such like rare drogues) true *Lignum Aloes* was not knowne to the Physitions or Apothecaries of *Europe*, for they used instead thereof a kinde of *Lignum Rhodium*, which *Ruellius* tooke to be *Aspalathus*, and but that the *Venetians* of late dayes by their travell and search, both in *Cairo* and the East Indies, caused some of the true sort to be sent unto *Venice*, and was upon view and tryall approved, the *Portugalls* Sea voyages to the East Indies, did first make it knowne in these later times to Christendome: but now in our Droguist and Apothecaries shops there is much variety and counterfeit stuffe obtruded on the ignorant, divers sorts being to be seene, and yet scarce one of them true *Lignum Aloes*, having those markes and notes formerly set downe, and acknowledged by the Ancients, which are the onely true notes whereby to know the best: and such no doubt is our best sort, which are knobbed or uneven peeces, very brittle, and breaking short, somewhat blacke on the outside, and more gray and discoloured within, of a very small sent, untill it be burned; yet I have seene with Master *Tradescant* the elder before he dyed, a great peece of true *Lignum Aloes*, and of the best sort, as bigge and as long as a mans legge, without any knot therein, which as he said our King *Charles* gave him with his owne hands, but was here kept before, and accounted by many, as a great religious rellicke, even to be a peece of the wood of that Crosse, whereon our Saviour was crucified, and therefore was fetched away againe from his Sonne, to be kept as a monument or rellicke still: but this is like all the other rellickes in the world, even meere Impostures, for assuredly if all those peeces of wood, that are or were to be found in the world, said to be parts of that Crosse, were all set together, they would goe neere to make one, yea many cart loads full: yet so fond and superstitious are men to beleeve lies rather then truthes, that they will rather kill the gaine sayers, and thinke that therein they doe God good service, then be wise to see their errours. The other sorts which are smooth and plaine, with long graines, are no true *Lignum Aloes*, although so called, being neither of that worth in price, nor goodnesse in effect. The propertyes whereof are very cordiall for the heart, and comfortable for the head and braine, helping the memory, and warming and drying up the defluxions of rheumaticke humours on those parts, for it is hot and dry in the second degree, a little astringent and bitter, and of subtill parts, it much conduceth to weake livers and fainting spirits, and strengtheneth also a languishing stomacke, helpeth disentries or laskes, and the Pleuresie.

Although the subject matter of this whole worke is the description of Plants, and of no other things, yet I thinke it materiall to this Classis and among the other Physicall Drogues, to treate of a few others that are not so; especially such as are best knowne.

## CHAP. II.

### *Ambra Citrina.* Yellow Amber.

YEllow Amber is called ἤλεκτρον by the Greekes, *Succinum* by the Latines, and *Carabe* by the *Arabians*, and in the Apothecaries shops, and is of sundry colours, some peeces being whitish, some yellow, paler, or deeper, and some of a very deepe red colour, and darke, all the other being cleere and transparent, but much more being polished: It is generally taken to be a kinde of liquid *Bitumen*, whose Springs and Fountaines are in the *Germane* Seas, and running into peeces, some greater and lesser then others, and is taken up with iron hookes, being soft under water, but hardning in the aire like Corall: that which is white, as being accounted the lighter and sweeter is the best for medicine, as the yellow for mechanicke uses, and being rubbed a little while, will then draw unto it strawes, and other such like small things, as the Loadstone doth iron, it will also burne like Rossin or *Bitumen*, with a strong heady sent, and the pouther thereof cast into the flame of a candle or other light, will make a sudden flash like lightening, and being so bituminous it yeeldeth an oyle, being destilled in a retort, which although at the first it is very red, and smelleth very fierce and strong of the fire, almost odious, yet by being sundry times re-distilled, it becommeth so rectifyed, that both sent and colour is so farre amended, that it is then fit to be used. The Physicall properties of Amber are many, for being moderately hot and dry, being burned on quicke coales, the fumes received to the head, doe much helpe the moist destillations thereof on the eyes, teeth, nose, or stomacke, and is very convenient for those that have the falling sickenesse, to lessen their fits, and to restore them: it is good to provoke womens courses, and singular good to helpe the strangling of the mother, and helpeth women with child, both to goe out their full time with ease, and to hinder their miscarrying that are subject thereunto, to take halfe a dramme of the pouther in a reare egge, or in Wine three or foure mornings together, and this also helpeth them that have the whites, and men that have the gonorrhæa or running of the reines, constraineth the flux, and strengthning the parts very much, and is a certaine remedy for those that have their urine stopped many dayes together, causing it to avoid plentifully, being taken in Saxifrage water; it is also very good for old coughes, and those that are fallen into a consumption, to take the pouther thereof mixed with Conserve of red Roses in the mornings fasting, and is very availeable for joynt aches, and the running gout. The Chimicall oyle of Amber being taken inwardly, three or foure drops in a little Muscadine doth wonderfully ease the stone, and the stopping of urine, or strangury making it by droppes: two or three drops used outwardly on the temples, the nape of the necke, or behind the eares, doe warme and dry a cold moist braine, discusseth winde in the eares and head, and strengtheneth the memory, and is a singular helpe in all cephalicall diseases.

## CHAP. III.

### *Ambergrisea.* Ambergrise.

AMbergriese is better knowne to most by sight what sort is better then other, then what it is, or whereof it commeth: the opinions of Authours are very variable hereof, some supposing it to be the spawne of the Whale, others the recrement of long continuance in the belly of the true Whale (that hath no teeth and eateth soft fishes) which it casteth forth at certaine times, and by the agitation of the sea is cast on shore; some others take it to be the excrement of certaine great sea fishes, and some to be the fome of the sea: all which opinions are utterly erronious, having no shew of truth in them; for although Amber in the *Ethiopian* language, signifieth a Whale, as well as Ambergrise, and yellow Amber also, from whence rose that vulgar opinion of being the spawne of the Whale, or because that in the belly of a Whale (as *Monardus* relateth it) taken about the *Canary* Islands, there was neere an hundred pound weight of Amber found, but in an hundred more taken afterwards, was none at all found; Yet the most likely and certaine received opinion of the most judicious is, that it is a kind of *Bitumen* (as the yellow Amber is before said to be, and therefore have both one name of Amber, being so neere one to another in their originall) whose springes are in the Rockes of the Sea (or as some of the Auncients supposed grew on the Rockes, like Mushromes on trees) condensate into that forme and substance usually observed, having that oylinesse or unctiousnesse is in, it from it owne originall, and being light is carryed by the waves of the sea, unto the shores of sundry Countries and climates: *Iosua Ferrus* relateth the originall thereof as of his owne knowledge, and that untill it hath attained the full maturity, it hath not that true sent of Amber, as after, and saith that he had seene divers such great peeces, that had not attained their true sent. And although the *Ethiopian* coast, from *Mozamlique* and *Sofala* to the Islands of *Maldiva*, and beyond them to the East, doe most abound with Ambergrise, yet are not the coasts of the West Indies in sundry places without it, nor yet these of *Europe*, in severall parts, and even our owne, and the *Irish* coasts have yeelded it oftentimes, and in severall peeces and quantity, yet neither so much nor so great as in other Countries: for *Garcias ab Orta* saith, the greatest peece that ever he saw, was a peece of fifteene pound weight, but there hath beene seene as it is set downe by Authours, some peece well neere an hundred pound weight. For the choyse thereof, seeing there is much variety in the colour, and some in the substance, as white more or lesse, or gray lighter, or darker, or enclining to rednesse or blackenesse: that which is not very white, as being usually very dry, but grayish more or lesse, and either with spots and veines, or without, so as it be fat, that is, upon a knives point, or such like thing, heated will shew oylie, is accounted the best, having the peculier sent belonging thereto, which is most neere unto dry cow dung, in my opinion, the blacke sort is the worst. The properties of Ambergrise are these: it is hot and dry in the second degree, it warmeth, resolveth, and strengtheneth, what way soever it be taken: it easeth the paines in the head, being dissolved in a warme morter, and mixed with a little oyntment of Orenge flowers, the temples and forehead being annoynted therewith: it comforteth also the braine, warmeth and resolveth the cold defluxions of humours thereon, and on the nerves and sinewes: it doth likewise comfort and strengthen the memory, the vigour also and spirits of the heart, it is singular good for women troubled with the mother, to be applyed to the place, it helpeth barrennesse proceeding from a cold cause: it is conducible to Epilepticke persons, to smell often thereunto, which causeth their fits to be both lesse violent and permanent: it doth most conveniently agree with aged persons, to warme, comfort, and strengthen their cold decayed spirits, adding vigour and lustinesse to them, and is accounted conducible to venereous actions.

## CHAP. IV.

### *Amomum.* Amomum.

EVen as I said before of *Lignum Aloes*, and in the last Classis of the true *Balsamum*, so much more may be said of *Amomum*, that the foregoing times for many ages had utterly lost the knowledge thereof, and is yet to this day held doubtfull, as the *Balsamum* is, with many learned men, both in other and our owne Country, whether the right be to be found in *rerum natura* or no, and therefore formerly many did obtrude divers things for it, as the *Rosa Hiericutitina* by some, and *Pes columbinus* by others, which is a kind of Cranes bill, called Doves foote, both which errors *Matthiolus* hath sufficiently confuted, *Quatranius* also tookthe *Myrtus Brabantica* our Gaule to be it, and then as *Matthiolus* saith, a small seed came to be taken for it, and therefore called *Amomum Germanicum*: but *Garcias ab Orta*, who lived many yeares in the East Indies, declareth that he saw a branch of *Amomum*, which the Physitions of *Nizamalucco*, the King of *Decan* gave him, being brought as they said among other drogues out of *Asia*, *Persia*, and *Arabia*, for the Kings use, which as he saith, he found agreeable to *Dioscorides* his description there of, and withall was very like unto a Doves foote, and called *Hamama* by the *Arabians*, which signifieth the same thing, that is, a Doves foote: but both he and *Valerandus Donres* were deceived with the same thing, brought from *Ormus*, in being so taken there generally, & both the *Amomum* & *Amomis* are set forth in the figures by *Clusius* in his *Scholia* on the same place in *Garcias* and here also. All these opinions and every of them are utterly false, and no way answering the truth of the thing, and *Dioscorides* his description: for of late dayes there hath been sent to *Venice* from the East Indies, by one *Martinellus* a famous and curious *Italian*, in the search of rare drogues, the true *Amomum*, which although it hath beene opposed by divers learned men, yet *Maroneus* of *Padoa*, hath in a little treatise thereof, so exemplified it and comented upon every part of it, and comparing *Dioscorides* with *Pliny* together, that it is now generally accepted of almost every where, to be the right and genuine thing, the description whereof, I meane so much as was sent, is on this wise: It is a bunch or cluster of whitish round berries, somewhat like unto Grapes for the outward forme and bignesse, but else very like unto *Cardamomes* within, yet bigger and rounder, having within the outer whitish thinne shell or skinne, sundry blackish browne seedes close

thrust

*Amomum genuinum & spurium.* True and false *Amomum.*

2. *Amomum aliud quorundam & Garyophyllum Plinij Clusio suspicatum.* Another sort of bastard or false *Amomum* suspected by *Clusius* to be *Pliny* his *Garyophyllon.*

thrust together, very like to the inner seedes of *Cardamomes*, but larger and of somewhat a fiercer piersing sent, smelling somewhat like unto oyle of spike, which made *Clusius* to thinke it had beene seasoned therewith, and of a sharpe hot and quicke taste. The properties whereof are these: It is heating, binding, and drying, procuring sleepe and rest, and easing paines in the head, being applyed to the forehead, it digesteth and discussetb inflammations and Imposthumes, and helpeth those that are stung by Scorpions: being used with *Bassill*, it helpeth gouty persons, and mervailously easeth the griping paines in the belly and bowels by reason of wind, to swallow three or foure of the seeds, and for the mother in women, taken in that manner, or made into a pessary and so used, or else in a bath, it is convenient both for the liver and reines, and is an ingredient of chiefe account, in great Antidotes that are preservatives. The false or bastard *Amomum*, which as it is likely is the same that *Garcias* saith was held for true in the Indies, and which *Clusius* saith in his Annotations upon that Chapter of *Amomum* of *Garcias*, *Valerandus Donres* received from *Ormus*, is by him thus described. They were like the toppes of some bushes consisting of a number of small branches, so thicke set with very small leaves that scarse any stalkes could be seene but leaves onely, somewhat like unto the stake with leaves of the sea Spurge, the ends of them so closed that they did in some sort resemble a flower or Rose, and the whole branches together, the foote of a feather footed Dove, from which likenesse it is probable arose the falsification, this had no singular good sent or taste to commend it. The very like hereunto saith *Clusius* he received at *Vienna* in *Austria* from *Constantinople*, which they there used for *Amomum*.

2. *Amomum aliud quorundam & Garyophyllon Plinij a Clusio suspicatum.*

Another sort of bastard or false *Amomum* suspected by *Clusius* to be *Pliny* his *Garyophyllon.*

Because this also hath beene by divers received for *Amomum*, and so sent to our Drugists, I thinke good to adjoyne it therewith, for some resemblance of the whole branch, although *Clusius* setteth it with the Cloves, which as he saith it is somewhat like in sent, but I thinke he referreth it to the Cloves, rather for *Pliny* his name of *Garyophyll*[illegible] r in my sent and taste, it hath little affinity therewith, but yet hath some correspondence with *Pliny* hi[illegible] notes or desciption thereof, and therefore I will give you *Clusius* his figure and description. *Iames G*[illegible] while he lived, an Apothecary after he had beene a Druggist in *Limestreete London*, in the yeare sixeteene hundred and one, sent *Clusius* some of this fruite as they grew, which were somewhat like Pepper cornes (but those that I have by the name of *Amomum*, and I thinke are the same with his, are browner and bigger all for the most part, then any Pepper graine,) some bigger and lesser, rugged and browne, and easie to be broken, which had blacke round seedes within them, to be divided into two parts, smelling as well as tasting like Cloves: this fruite or berries grow many clustring together like a bunch of Grapes, (each whereof hath a little crowne at the head, somewhat like an Hawthorne berry) two or three sometimes together on a stalke: this had likewise some leaves still abiding on the branch, and were of sundry sizes, although all of one forme, that is somewhat long and round, and round pointed, not dented at all about the edges, but smooth, and many veines therein, of a brownish ash-colour, and growing opposite on the stalkes. This is the cheife parts of his description. We have not knowne it used for any disease, more then that being obtruded for *Amomum*, some more audatious then wise

wise, have put in their compositions instead of the right, but by the taste as *Clusius* also noteth it, it might seeme to be availeable to many good uses if they were tryed.

## CHAP. V.

### *Anacardia.* Anacardes or *Malacca* Beanes.

A *Nacardium* is a fruite like unto an heart, growing on trees plentifully in *Cananor* and *Calecut*, *Cambaya* and *Decan*, as *Garcias* saith, (and as some say on those mountaines in *Sicilia* that cast forth fire, but I somewhat doubt thereof) greater then our greatest Beane, and called by the *Portugals Fava de Malacqua*, of the *Arabians Balador*, and of the Indians *Bibo*, whose outer skin or huske is of a darke red colour, betweene which and the white edible kernell, lyeth a certaine liquour or viscous substance, of a fiery red colour while it is fresh, and of a sweetish, but somewhat hot taste, which is the true *Mel Anacardinum*, but instead thereof, because we cannot have them so fresh, that we might take forth this substance, some use to boyle the fruite being broken or bruised in honey, and then call it *Mel Anacardinum*, but of farre lesse effect. The whole fruite saith *Garcias*, is familiarly eaten while they are fresh, as also being pickleed like Ollives, in all those parts where they grow, but as he saith, when they are dry, they use them as a causticke, to take away wens, &c. The qualities hereof are set downe by *Serapio* and *Avicen*, who although they make it to be of a delitery and poysoning property, by overheating and burning the blood, being hot and dry in the third, if not in the fourth degree, which *Garcias* beleeveth not; yet they say that the fruite helpeth the sences that are weake, and the memory that is decayed, and comforteth the braine, and nerves that are subject to the palsie that commeth through cold: *Garcias* saith that in India they use to give the whey wherein the fruite hath beene steeped, to those that are short winded, and to those that have the wormes.

*Anacardi.* Anacardes or *Malacca* beanes.

## CHAP. VI.

### *Cajous.* The *Cajous* or Apple Beane.

BEcause this fruite comming from *Brasill* and called by the people there *Cajous*, is in divers things like unto the *Anacardes*, I thought it not amisse to give you the knowledge thereof next thereunto, with the description of it, as *Clusius* hath recorded in his *Scholia*, on the *Anacardes* in *Garcias*, for I finde some other Authours to have made mention of it, as *Christophorus a Costa*, *Lugdunensis*, *Linschoten*; *Baptista Ferrarius* who set forth a small plant thereof of one yeares growth, yet none have added any thing unto him. This tree (saith he) is great, having leaves like the Peare tree, but rather like Bay leaves in those that are new sprung up, thicke and, of a pale greene colour: the flower is white like to the Orenge flower, but thicker with leaves, but not so sweet as they, the fruite is like unto a Goose egge, both for forme and greatnes, of a very yellow colour, & sweet, full of a liquour like unto that of a Citron, that is called *Lima*, which is eaten by them with great delight, yet somewhat sharpe, and *Acosta* saith the same, and as it encreaseth the nut groweth lesse (although *Thevet* in the 61. Chapter of his description of *America*, contraryeth this manifest truth) not having any seed within it, but at the end of this fruite groweth forth this nut, which being put into the ground doth spring up like the stones or kernells or any other fruite, being of the fashion of an Hares kidney, of an ash-colour sometimes declining to rednesse: this nut hath a double rinde, or shell betweene which is a certaine spongy substance, full of a most sharpe and burning oyle, the kernell within being as sweet as a Pistack nut, covered with a thin ash coloured skin, which is to be taken away, and is said to be a stirrer up of Venerious actions, and therefore

*Cajous arbor cum suo & tenella planta.*

used

used by them, being first lightly toasted: the sharpe liquour or oyle is used by them against scabbes, and is good also for running tetters, and ringwormes. I have here given you the figure of the nut it selfe, and of the first yeares shooting of the tree, as *Baptista Ferrarius* hath exhibited it in his Booke *de florum cultura*. *Acosta* further saith, that they use in the Indies to pickle them as they doe Ollives, and eate them to procure an appetite, to stay castings, and to helpe the weakenesse of the stomacke.

## CHAP. VII.

*Anisum exoticum Phillipinarum Insularum.* A strange Anisseede like seede of the Indies.

WE can give you no knowledge of either roote leafe stalke, or flowers of this strange plant, brought from King *Phillips* Islands neere unto *China*, and thereupon called *Phillippinas*) but of the toppes onely, with the huskes and seed in them, brought by Sir *Thomas Candish*, in his voyage of the Globes circum-navigation, and given to Master *Morgan*, Queene *Elizabeths* Apothecary, and to Master *Iames Garret*, of whom *Clusius* received them, and giveth this description thereof. It was a stalke with flat umbels of seed, as large as those of *Archangelica*, and peradventure larger, sustained by thicke footestalkes, and set round at the toppe, in a round forme one by another, consisting of sixe, eight, or more huskes of seed, which were not parted in two like our ordinary Anisseede, but each of them had divers round smooth shining ash-coloured seed within them, like unto *Orobus*, the huskes were about an inch broad of a brownish colour on the outside and rugged, openning at the toppe into two equall parts, and although divers were empty, yet some contained such seed as aforesaid, the smell and taste of them was very like unto Anisseed, whereupon it was called Anise by them that sent it: but Master *Garret* sent the right name, whereby it was called in the Islands, one of them being brought along with them, who set the name in *China* Characters, which as *Clusius* saith he could not imitate, but was *Damor*, every letter being written under the other downewards.

*Anisum exoticum Phillippinarum Insularum.*
A strange Anisseed like seed of the Indies.

## CHAP. VIII.

*Asa dulcis & fœtida.* *Assafetida* and the other *Asa*.

ALthough I have spoken somewhat of *Asa dulcis sive oderata & Assafetida* in the Chapter of *Laserpitium* among the umbelliferous plants, yet because I said but little of them there, reserving them for this place, I will here entreate of them more largely. There is none of the ancient Authours either Greeke, Latine, or *Arabian*, that hath made any mention of *Asa*, either *dulcis* or *fœtida*, but was first depraved by the Druggists and Apothecaries in forraigne parts, that in stead of *Laser* said *Asa*, from whence ever since the name of *Asa* hath continued, and afterwards divided into *Dulcis* or *odorata*, and *fœtida*, from the differing sorts of goodnesse pureness and sent thereof, when as they are both of a strong smell, yet one much more then another, the *Asa fœtida* being of so evill a sent, that the *Germanes* call it *Teuffelz drech*, that is, *diaboli stercus*, Devils durt, and is very neere the sent of *Storax liquida*, if it be not the same, relented and brought into a liquid forme, the foote or sediment declaring it plainely, and is accounted with them to be sweet, being of a strong unpleasant savour, rather then sweet to us, so is the *Asa dulcis & odorata*, called sweete in comparison of the other, called *fœtida*, because being purer, it hath a more unpleasant sent and taste. For as *Garcias* saith *Asa* is called *Altihi* by the *Arabians*, which is the *Laser* of the Greekes and Latines, as the plant being called by them *Anjuden*, and *Silphium* by the Greekes and Latines, but *Jmgu* and *Imgara* by the Indians, the one when it is clensed and purified from the drosse being cleere and yellow as Amber, the other foule and impure, and are so familiarly eaten, as *Garcias* saith by the Indians, in their meates, brothes, and sallets, and medicines, that they scarse eate any thing, that is not seasoned therewith, and is very pleasant to them being used unto it, but loathsome to others, the richer sort using the purer, and the poore the course: divers heretofore have mistaken *Benzoin* for *Asa dulcis*, and I doubt the errour is not yet quite extinguished, and *Matthiolus* confesseth his former errour therein, which upon better consideration he amended, *Benzoin* being the gumme of a tree, and being not so hot as *Laser*, which by *Galen* his appointment had for its substitute *Euphorbium* being growne old. The *Asa dulcis* being in former

times well knowne and used, is now adayes quite lost and forgotten, being not brought into these parts, but the *Assafetida* hath a continuall residence and recourse unto us, and is as *Garcias* saith, the true and onely *Laser*, or *Laserpitium* of the ancients, and so accepted generally by the *Arabians* in India, and say they erre mightily that make them differing. It is generally used in our dayes for the rising of the mother in women, as all strong and evill sented things be, which depresse it, and is singular good to be put into hollow aking teeth, to ease and take away the paines: One saith he tasted of it for a tryall in a cold time of the yeare, and after a little walking he found himselfe possessed with a gentle sweate, both head, armes, and body, and shortly after found his stomacke better disposed to his dinner then at other times before, and digesting it better. *Garcias* saith the Indians use it to take away the loathing of the stomacke to meate, and to strengthen the weakenesse of it also, and is much used by them to provoke unto Venery, and causeth one to expell winde mightily, which thing was tryed by a *Portugall* as *Garcias* relateth it upon an Horse, whom the King of *Bisnager* would have bought, but that he was over subject to breake winde, but after that the *Portugall* had cured him thereof the King bought him, and asking how he cured him, he answered him with *Assafetida* given in his provender, no mervaile said the King, if he were cured with the gods meate, yea rather with the devils said the *Portugall*, but softly, and in his owne language for feare of being overheard.

## CHAP. IX.

### *Balsamum Peruvianum*, The West Indian *Balsamums*.

OF the true *Balsamum* I have entreated in the last foregoing Classis or Tribe, but there have been divers other sorts of liquours called *Balsamum* for their excellent vertues, brought out of the West Indies, every one of which for a time, after their first bringing were of great account with all men, and bought at great prices, but as greater store was brought, so did the prices diminish, and the use decay, when as it was the same thing and of the same vertue it formerly was, such is the inconstant course of the world in all things. One sort of *Balsamum* which is of most frequent use with us, is called blacke or browne Balsamum, because the colour is blackish, and tending to browne being dropped forth, which as *Monardus* saith is gathered from a tree, somewhat bigger then a Pomegarnet tree, (whose fruite or long pod I here shew you, as I received it, with a very browne almost blacke colour, and smelt so like this *Balsamum* or *Benzoin*, that I am cerrainely perswaded it was gathered from this tree) not by incision, as the juyces, liquours, and gummes of other trees (which yet this tree doth also in small quantity, yet being white, and so precious with the Indians, that they will not part with any of it) but made after the manner that the Indians use to draw forth the juyces and liquours out of all their other trees, which is by cutting the branches, and the bodies also sometimes of trees into small peeces, which after the boyling in a great quantity of water, the oyle swimming on the toppe, after it is cold is scummed of by them and reserved. This is of a thicke, yet running consistence, and of a sharpe and somewhat bitter taste, but of an excellent fine sent, comming neerest unto *Benzoin*, but will not long endure, being rubbed on any thing that is kept in the ayre, but never loseth it sent being kept close in a glasse or the like. This is used inwardly and outwardly for divers good uses, and although in some it causeth a kinde of loathing to the stomacke, if it touch the tongue, in drinking foure or five droppes in wine fasting, yet it helpeeth the weakenesse of the stomacke, the Tissicke, and shortnesse of breath, those that are pursie and the paines and difficulty in making water, it moveth also womens courses, and causeth a good colour, and a sweete breath, rectificth the evill disposition of the liver, openeth obstructions, and preserveth youthfullnesse even in aged persons that have much used it, and helpeth the barrennesse in women: being outwardly used, it is singular good to heale any fresh or greene wound, and old ulcers, and sores also: it easeth paines in the head or necke, and swelling in any part of the body, the places thereof being annoynted therewith, or a cloth wet therein and applyed: it helpeth digestion, strengtheneth the stomacke, dissolveth winde, easeth the spleene, and the Sciatica, the strangury and stone, and discusseth all nodes and hardnesse of tumours, being applyed warme to the places pained: it warmeth and comforteth the sinewes, and keepeth them from shrinking.

*Fructus sive theca Balsami Occidentalis arboris.* The fruite of the West Indie Balsame tree,

*Balsamum album.* Another white and very cleere Balsame of a very sweet sent *Monardus* saith, was brought likewise from the continent of *America* in some good quantity, which was taken by incision from very great trees full of branches to the bottome, whose outer barke is thicke like Corke, under which there is a thinner, from whence being slit the *Balsamum* droppeth forth, the fruite hereof is very small even no bigger then a Pease, and of a bitter taste, inclosed in the end of a long thinne white cod, wherewith the Indians doe smoake their heads against the paines thereof, and rheumaticke destillations: This liquour or *Balsamum* is accounted of much more vertue then the former, one droppe being said to be of more force and effect then a great deale of the other. There is another sort of precious *Balsamum* saith *Monardus* brought from *Tolu*, which is a Province betweene *Carthagena* and *Nombre de Dios*, and is gathered by incision from small low trees, like unto low Pines full of branches, but with the leaves of the *Carob* tree abiding greene alwayes, the manured yeelding more liquour then the wild, and is of great account with the Indians and *Spaniards*, being taught by them: it is of a gold red colour, of a middle consistence and very clammy or glutinous, of a sweete and pleasant taste, not provoking vomit, as other sorts of *Balsamum* will doe, and of an excellent sent like unto a Lemmon, whereof a droppe being let fall into the hand

*Balsamum de Tolu.*

hand, will ſmell egregiouſly through all the place. Vnto this *Monardus* attributeth all the vertues of the true *Arabian* Balſame, and much more then unto any of the former, which becauſe I would not make a double repetition of things, I referre you unto them.

## CHAP. X.

### *Bdellium.* The Gumme called *Bdellium.*

ALthough *Dioſcorides* hath given no deſcription of the tree that beareth *Bdellium*, nor any part thereof; yet *Pliny* in his twelfth Booke and ninth Chapter ſetteth it downe, that it is blacke or of a ſad forme, and of the bigneſſe of the white Ollive tree, having leaves like an Oke, and fruite like the wild Fig tree, which how truely expreſſed reſteth doubtfull, for *Lobel* ſetteth forth a ſticke of a thorny tree, found among drugges, with divers peeces of gumme cleaving to it, moſt likely to be *Bdellium* or Myrrhe, which are very like one unto another, being both gathered from cruell thorny trees, and *Thevet* ſaith, that he ſaw in one wood of trees, two thouſand of theſe ſorts growing mixed together, and that in ſuch countries that are ſubject to ſnow, yet the beſt Authours ſay that *Arabia* is the chiefe place where they grow, which I thinke never ſaw or felt ſnow, yet in *Geneſis* 2. *verſe* 12. we read that *Bdellium*, and the Onix ſtone, beſide Gold, grew in the Land of *Havilah*, which is interpreted to be Eaſtward from *Perſia*: ſo that both the tree and the gum thereof are called by one name, for the choyſe wherof *Dioſcorides* ſetteth downe that it ſhould be cleere like glew, fat on the inſide, eaſily melting or diſſolving, pure or cleane from droſſe, ſweete in the burning like unto *Vnguis odoratus*, (for ſo I conſtrue it although divers Authours doe diverſly interpret thoſe words, ſome making *Vnguis* to be a note of white peeces in the gumme, like the naile of ones hand, but in my judgement the *Vnguis* is referred by *Dioſcorides* to the ſweete fumes of *Bdellium* in the burning, whereunto it is like, for having ſaid that it was *ſuffitu odoratum*, he would rather ſhew what ſent it had, namely of *unguis odoratus*) and bitter in taſte, which are ſuch notes as we can hardly find in any that is brought to us, for we find little bitterneſſe in any, and leſſe ſweetneſſe in the burning of it or *Vnguis odoratus*, but ſtrong and unpleaſant rather, neither is it ſoft or eaſie to be diſſolved, but hard and not to be diſſolved equally, but into graines or knots without warmth, yet is ours of a ſad browne colour ſomewhat like glew, and much like unto Myrrhe, ſo that they are often miſtaken one for another, but that *Bdellium* is harder, dryer, and browner: but there are ſundry ſorts thereof as *Matthiolus* ſheweth, and *Bauhinus* in his note upon him, that he hath ſeene, for not onely in former times there was much adulterating of drogues, by the Indians as it was ſuppoſed, but moſt probable by the *Arabians* who were the chiefe Merchants for thoſe places, and for thoſe things, and I thinke the Iewes learned that art of them, and have exceeded them in cunning. The properties hereof are heating and mollefieth hard tumours, and the nodes of the necke, throate, or ſinewes, or of other parts, any way applyed; it provoketh urine and womens courſes, and breaketh the ſtone: it is good for the cough, and for thoſe that are bitten or ſtung by Serpents: it helpeth to diſcuſſe the windineſſe of the ſpleene, and the paines of the ſides: it is good alſo for thoſe that are burſten and have a rupture: it mollefieth the hardneſſe of the mother, and dryeth up the moiſtneſſe thereof, and draweth forth the dead birth.

*Bdellij fructus quibuſdam acceptus quem potius cuci Theophraſti fructum opinatur.*

## CHAP. XI.

### *Behen album & rubrum.* White and red Ben.

THe ancient Authours have beene both very briefe in declaring theſe two ſorts of Drogues, and are alſo not at one among themſelves what the true *Ben album & rubrum* ſhould be, for *Actuarius* and *Myrepſus* make the *Hermodactilli* to be Ben, how then can any of our Moderne Writers, find out the true Ben of the Ancients, yet divers have appropriated ſundry herbes unto them, but they have all come farre ſhort thereof, not onely in the thing, but eſpecially in the properties, *Cluſius* ſetteth forth a kinde of wild *Campion*, which as he ſaith, the learned Profeſſours at *Salamanca* in *Spaine* tooke to be the *Ben album* of the ancients, but is nothing ſo: *Dodonæus* ſetteth downe the *Papaver ſpumæum* which he calleth *Polemonium* to be it, and ſome take the wild Parſnep to be it: for the *Ben rubrum*, they of *Mompelier* call a ſmall ſort of wild Campion, others the red *Valerian* of *Dodonæus*, *Matthiolus* the *Limonium*, and others take the *Biſtort* roote for it; *Garcias* ſaith that ſome tooke the *Zedoaria* for one of them; *Anguilara* and *Camerarius* alſo ſuppoſe that the garden red Carret

ret, and the white wild kind of it, which the *Italians* call *Carotta bianco* are the red and the white Ben, which they and I also suppose may passe reasonable well as substitutes for them, untill the true may be knowne. But those things that goe under their names in the Druggists, and Apothecaries shops, are not knowne, what they are, but are certainely false, and not the things they should be. *Rauwolfius* saith that he found the true white Ben growing at the foote of mount *Libanus*, in a moist shadowy place, which the Inhabitants call *Behmen Abiad*, as they call the red *Behmen ackmar*: the description of the white sort he setteth downe thus: the leaves are great long and thicke, like unto the sharpe pointed Docke, upon long footestalkes, but having at the bottome of each leafe, foure other small ones standing by couples each against other, those that grow on the stalke are lesse, and without any footestalke, the toppe of the stalke is parted into some branches, each bearing at the toppes a knap or yellowish scaly head, out of which breaketh a yellow flower: the roote is long and full of joynts, but without any or very few fibres, very like unto Licoris both for forme and greatnesse, but white inwardly. They are say *Serapio*, *Mesues*, and other *Arabians*, hot and moist in the first or second degree, they comfort the heart, and are stirrers to Venery.

*Behmen abiad.* White Ben.

## CHAP. XII.

### *Benzoin. Benjamin.*

THe tree from whence this sweet gumme *Benzoin* is taken, is very great, faire, and high, largely spread and set full of branches, in a comely order, the leaves whereof are somewhat like unto those of the Citron tree, but lesser and not so greene, but grayish on the underside: from the body hereof which is great and thicke, and the wood very hard and firme, by wounding it as they doe other trees, is drawne forth the gumme, which is of divers sorts, for some is very red, and full of barkes and stickes which some take to be the sweetest, others is more pure or cleane, nothing so red, having many great and small white peeces of gumme in it, which is called the Allmonds of the gumme, another sort is blackish, which is said to come from the younger trees, and called as *Garcias* saith *Benini de Boninas*, and is sweeter then the last. Some saith he, call *Benzoin Benjaoi quasi filius Iavæ*, (which *Scaliger* correcteth, saying *Garcias* was mistaken in thinking that *Ben* in the *Arabian* tongue, signifyeth *filius*, when as he saith it is *lachryma*, and so *Benjaoi*, is *lachryma Iavensis*) and some, as *Ruellius Ben Iudæum*, deceived either by the neerenesse of the name, or because he thought that *Iudæa* was the naturall place thereof, and that it was a kinde of *Asa dulcis*, but without any truth or ground of reason, which opinion is yet held with divers who will still use it inwardly in place of *Lasor*: it is usually called in shoppes *Benjuinum*, and of some *Belzoinum*, and *Benzoin*, or *Benzoinum*: and of the Indians *Cominham*: There hath been sundry errours among learned men, about this gumme, for finding it to be so sweete, and of so delicate a substance and shew, they straight imagined that it could not be but of some singular vertue, and not unknowne to the Auncients: some therefore thought it to be *Cancamum* of *Dioscorides*, but yet as *Garcias* sheweth, it chiefly groweth in *Sumatra*, and *Sian*, and *Martaban* neere thereunto, of the *Arabians Lovan jaoy quasi thus ex Iava*, and *Vdo* at *Surrat*, *&c.* and not in *Arabia*, as *Dioscorides* saith *Cancamum* doth: some tooke it to be the best *Myrrha* called *Myrrha Aminea*, and some as I said before to be *Asa dulcis*, but *Benzoin*, besides that it was not knowne to the Ancients, it is not used inwardly in Physicke, neither by the Indians, nor by us that mistake it not, but is wholly spent in perfumes either water or oyle, pouther, Pomanders, burning perfumes or the like, and is of an excellent sent, where or howsoever it is used. *Bauhinus* seemeth to referre that slender long fruite of *Clusius*, *Exot. lib. 4. c. 11.* unto *Alpinus* his *Felfel tavil*, and that it was naturall of *Florida*, but *Vestingius* sheweth it to be farre otherwise, as shall be shewed in the Chapter of Pepper, but I rather thinke it is the fruite of this *Benjamin* tree, or of the browne *American* Balsame before set downe.

CHA.

## CHAP. XIII.

*Bitumen Iudaicum.* Dry Pitch of *India.*

THe *Bitumen* or dry Pitch, which the dead Sea in *Iudæa* casteth up at a certaine time of the yeare is set downe by *Dioscorides* to be of a shining purple colour, but that which is blacke, is adulterate, and *Matthiolus* saith that the *Asphaltum*, or *Bitumen* of the shops in *Italy* (and sowith us is a mixture, and not the true thing: *Dioscorides* saith it is had from *Phœnicia* (wherof *Iudæa* is but a part) from *Babylon*, the Island *Zacynthus* and *Sydon*: but that of *Babylon* which hath beene seene by many in these dayes, is held to be another thing, even the same that the builders of *Babel* used instead of morter to cement their bricks; but that of the dead Sea is only in use and the best, which dead Sea or Lake is of a great extent, yet diversly proportioned by Writers thereof, for *Pliny* as I find *Matthiolus* quoteth him, maketh it to be an hundred miles long, and in the broadest place five and twenty miles over; but Sir *Walter Ralegh* in his Chronicle, relateth *Pliny* to make it lesse then our Moderne Travailers doe, who judge it to be eighteene *Dutch* miles in length, that is 72. of ours, and two *Dutch* miles and a halfe in breadth, that is tenne of ours, accounting one *Dutch* mile to be foure *English*, *Iosephus* saith it is 180. Furlongs in length, that is two and twenty and a halfe of our miles, and 150. Furlongs in breadth, that is eighteene miles and somewhat more of ours, such variety there is in Writers: This Lake or dead Sea is (called by *Galen Lacus Asphaltites*) the same place where *Sodome* and *Gomorrha* with the other Cities stood, mentioned in *Genesis*, being then the pleasantest and most fruitefull valley of all those parts, exceeding *Hiericho*, and the parts thereabouts, which is about fifteene miles from it, and whose River runneth into it, and so drowned therein, yet no fish entereth into it; but now the tract of ground about it for a great compasse beareth a sad face, and is either utterly barren and fruitelesse, or beareth such fruite as is onely faire without and dust within, and the aire noysome and pestilent, by the thicke infectious vapours arising from it, and is neither moved by the wind, nor will suffer any thing to sinke therein, but will swimme on the toppe, and is not onely of a salt but bitter taste, which will corrupt any thing rather then preserve it, as salt Sea water will. There are other sorts of *Bitumen* in the World, as Historians report, as in *Cuba*, and sundry Fountaines neere the sea shore, casting it forth as blacke as Pitch, Another sort is in a Province of *Peru*, where the place is voyd of tree or plant, and giveth a fat liqnid *Bitumen* in this manner: Turfes of the earth, being laid on hurdles, the liquour dropping from them, by being set in the Sunne, is kept to heate and comfort any place affected with cold humours and tumours, cureth wounds, and is used for those griefes whereunto *Caranha*, and *Tacamahaca* serve: it is of a strong smell, and of a blackish red colour. The Inhabitants about this Lake, gather this *Bitumen* or Pitch, being an oyle or liquid substance on the water, and hardned by the aire, and spend it chiefly in pitching their Ships, but medicinally it discusseth tumours, and swellings, and mollefyeth the hardnesse of them, and keepeth them from inflammations, and is of singular good use for the rising of the mother, and for the falling sickenesse, to be burnt and the fumes thereof which are strong smelled unto: it bringeth downe womens courses taken in Wine, with a little *Castoreum*, it helpeth the biting of Serpents, the paines of the sides and the hippes, and dissolveth congealed blood in the stomacke and body.

*Petroleum quasi petræ oleum* or oyle of *Peter*, is a thinne reddish liquour, thinner than oyle of Ollives, and almost as thin as water, and is accounted to be a liquid *Bitumen*, and thought to be the *Naphtha* of *Dioscorides* by *Matthiolus*, because it is so apt and easie to take fire, even by the ayre thereof, and is gotten in sundry places of *Italy*, distilling of it selfe out of a Mine in the Earth, and in *Hungary* also, in a certaine place, where issuing forth in a well together with the water, the owner of the place thought to have the chinkes stopped up with morter, which could not be done without light, the workeman therefore taking a close lanthorne with a light in it, went about it, and being gone downe into the well to stoppe it, very suddainely, the *Peter oyle* taking fire, flew round about the sides of the Well, and with a hideous noyse and smoke, like the cracke of a peece of great Ordinance shot of, it not onely cast forth the Workeman dead, but blew up the cover of the Well into the aire, and set on fire also some bottles of the oyle that stood by the Well, and many persons that stood thereby were scorched with the flame. This oyle of *Peter* is a speciall ingredient to make wilde fire, and is of a very hot and piersing sent and quality, and therefore is used for cold aches crampes and goutes, and to heale any greene wound or cut, suddainely, a little thereof being put into the oyle of Saint *Iohns* wort and used.

---

## CHAP. XIV.

*Blatta Byzantia sive Unguis odoratus.* The sweete Indian sea fish shels.

THis Indian shell, of some sea fish, hath beene the subject of some controversie among the learned: for *Fuchsius* would make the *Onyche* of *Dioscorides*, and the *Blatta Byzantia* or *Unguis odoratus*, to be differing things, and then againe, he would make the *Blatta Byzantia* to be a bone in the mouth or fore part of the nose of the shell fish *Purpura*, or purple Periwinkle, and this he doth twise expresse in his Annotations on *Nicholaus Myrepsus*, in the composition of *Aurea Alexandrina*, and in *Diamargariton*, into both which compositions the *Blatta Byzantia* are to be put, but *Matthiolus* contesteth against this his opinion, and saith that these sweete shells called *Conchula Indica* or *Unguis odoratus* are taken by *Serapio* and *Avicen*, and the latter Greeke writers, to be no other thing then the *Blatta Byzantia*. And againe that never any Writer accounted that bone in the nose of the fish *Purpura*, to be sweete or numbered among other sweete things, but that the ashes of their shells being burned was drying, and served to clense the teeth, and to restraine the excressences in the flesh, to clense ulcers, and to bring them to skinning: but on the contrary side, the *Arabians* have alwayes used the *Blattæ Byzantiæ*; because they were of an astringent

quality, of thin parts & did participate of a kind of sweetnes, and is good in the diseases and weakenes of the stomacke, the ill disposition of the Liver, the fainting of the heart, and the rising of the mother in women, and as *Dioscorides* saith is good also for the falling sicknesse, to burne them under their noses, that the fumes may ease their fits, and that none of these qualities were ever attributed to the purple Periwinckle shell. *Dioscorides* writeth that the best come from the red sea, and are white and fat, that is, will easily burne (but such did I never see) and that those that come from *Babylon* are blacke, but the fumes of both are like unto *Castoreum*, which argues those not to be right that are in our shops, although some doe differ from others in the sise, as is expressed in the table. Yet *Matthiolus* setteth forth in his Commentaries on *Dioscorides*, a certaine small long hollow shell, almost like a tooth, which I rather take to be the *Dentali* of the ancients for *Unguis odoratus*, being likely such as were used in his time, which I have here expressed, in the same table with those sorts that our Drugists impose on us, being of two sorts, of broad and somwhat hollow brown shels, the one smooth, and the other rugged, and the one smaller then the other.

*Blatta Byzantia sive unguis odoratus.*
The sweete Indian Sea fish shell.

## CHAP. XV.

### *Bolus Armenius.* Bolarmoniackē.

THe severall sorts of Bole or Bolarmoniackē that arē to be seēne at sundry times with us, doē testifie that we scarce know which to accept for the right, for *Galen* saith it is of a pale colour, and *Pliny* making three sorts, red, and lesse red, and a middle sort, sheweth that both red and pale were so called, and used alike, and most of the sorts that we have, have the notes and markes of the true, that is, it is a firme or close earth, heavy without gravell or stone, and for the most part wholly of one colour, without discoloured parts; which doth shew that not onely that *Bolus Armenius* which some call *Orientalis*, but many other of the finer sorts, found in other places, not onely as a mine of it selfe, but in the mines chiefly of iron, and some in those both of gold, silver, and copper, may safely be used for some of the same purposes: but because they all or most of them doe colour the hands or fingers of them that touch them, many have supposed that it may not unfitly be referred to *Galens Rubica Lemnia*, which was differing from the *Terra Lemnia*, because it coloured the touchers hands, which *Terra Lemnia* did not: or may be the *Rubrica Sinopica* of *Dioscorides*, which was of a liver colour, although peradventure in his time the *Alexipharmicall* qualities were not knowne to him or in his time; as his *Rubrica Fabrilis*, so called because Carpenters did use to strike their lines therewith, as we doe now with chalke, may be our common Bolarmoniacke, which is courser, more brittle, and used onely outwardly to stanch bleedings. All the best sorts of Bole with us, have such a clammy or sticking quality, which the ancients mention not, that is, if it be touched with the tippe of the tongue, it will cleave very fast thereto, and the stronger it cleaveth, and the harder it commeth from the tongue, the better is the Bole accounted of. And is used as a speciall remedy in all contagious diseases of the pestilence, small poxe or the like, and in pestilent feavers, and against poysons, and the venome of Serpents: it hath also a binding property to restraine all fluxes of the belly or of the sperme, or of womens courses.

CHAP.

## CHAP. XVI.

*Borax.* Borace.

BOrax or *Borrax* called by the Greekes *Chrysocolla* from the property of sodoring of gold; and *Tincar*, or *Tincal* by the *Arabians*, is said by *Garcias* to be a Minerall matter, gotten out of a Mine of earth, in a mountaine, about an hundred miles off from *Cambayette*, but this is not the *Chrysocolla* of the Auncients, *Dioscorides*, *Galen*, and *Pliny*, which in their times was of a greene colour, found in Mines of sundry mettals, made into pouther and washed often, and prepared for the purpose; but ours is made by many in our owne land as well as in others, by art as Allome is, into small pure white peeces. of no taste or but wallowish; and is easily beaten into pouther; the substance whereof it is made, being brought us out of the East Indies, and no place else that I know, and is certaine white stones, put into, or wrapped in fat or grease, which is called unrefined Borace, and so brought to us, untill it be refined, as we have it to use: the properties whereof besides the sodering of gold, silver, copper, &c. is of good efficacy, not onely inwardly taken to binde fluxes of the belly, as laskes and the like, but the gonorrhea *passio*, or running of the reines, but outwardly to soder up any cut or fresh wound in the flesh, and is often used also with other things as a *fucus* for the face, &c.

## CHAP. XVII.

*Cambugio quibusdam Catharticum aureum.* The golden yellow Indian purger.

THis *Cambugio* as it is of late importation, so it is likewise of small knowledge unto us, whereof it is made, for but onely what we see of it to be a solid peece of substance, made up into wreathes or roules, yellow both within and without, and giving a yellow colour upon the moistening of it, we know not as yet, neither can we learne truely, whether it be a gum or hardned juyce, which it is the more likely to be of the two, because it will so easily dissolve in water, although some suppose it to be the juyce of *Euphorbium*, others of the purging Thorne: some thinke it to be made of Scammony, or Tithymall, others of Spurge, and some of the greater Celandine, other of the middle rinde of the Aldar tree, and lastly *Bauhinus*, because he would say somewhat, maketh a *quid si forte*, what if it be not the juyce of the flowers of *Ricinus* dryed, and I say it is most likely to be the juyce of a peculiar herbe of that Country, that giveth such a yellow juyce as Aloes. It hath gained a number of names, partly from the sundry nations languages, and partly from the mistakings and ignorances of people: as *Ghitta jamaa*, or *Gutta gemou*, or *Gama gitta*, or *Gutta gamandra*, or *Cattagauma*, or *Cambici*, or *Crambici* or *Cambugio*, and some others also, which I willingly omit; it is brought unto us out of the East Indies, and some say from *China*. The properties hereof are to purge both by stoole and by vomit, and is of much use with divers persons of good judgement and quality, who give from three or foure graines unto ten or twelve, or to a scruple or halfe a dramme, according to the age and strength of their bodyes, and worketh gently with some, evacuating forth crude flegmaticke humours from the stomacke, and wheyish from the bowels without any trouble: but contrarily with others it worketh very churlishly, and with much perturbation of the stomacke: Some also use to make small pilles of it, and give it in that forme, especially if the humours be stiffe, and not easie to be avoyded, and for that cause some will adde a little Scammony unto it to helpe the slow working in some bodyes, some also to correct for the tenderer bodies will give it in the pulpe extracted from Currans in white Wine, as a corrector of the quallities, and some in the infusion of Roses.

## CHAP. XVIII.

*Champhora.* Camfire.

CAmfire, called *Caphura* from the *Arabians Cafur*, is such a subtle thing, both in substance and nature, that although it is the gum or liquour of a great vast tree, (like to a Wallnut tree, whose wood is somewhat solid and firme, and of an ashcolour like unto Beech, or somewhat blacker, the leaves are whitish like unto Willow leaves, but neither flower nor fruite have beene observed, yet is likely to beare both) partly distilling forth of it owne accord, but chiefly by incision, which commeth forth cleare and white, and hath no spot therein, but what it acquireth from their foule hands that touch it, yet what we have and use, seemeth plainely to be so made by art, being cast as it were or sublimed into broad round pannes or dishes, and little above the thickenesse of ones thumbe, cleere, white, and transparent, but not to be made into powther of it selfe, (although it is somewhat brittle, and will breake into many small peeces) without the helpe of a blanched Allmond, or some other such like unctuous thing, which hereby will reduce it into fine pouther: neither will it be easily dissolved in cold water, but by warmth will be resolved like unto fat, being easily set on fire, and will burne in the water, serving for wild fire with the other things, and is of a very strong fierce sent, both sent and substance vanishing away, if it be exposed for a while to the open aire; yet the wood being made into severall workes, will smell thereof a long time: Some take it to be hot, because it is of such tenuity of parts. *Rhasis* saith it is cold and moist, but *Avicena* saith it is cold and dry, and that it causeth watchings and wakefullnesse, and quieteth the senses of those that are hot, which are contrary one to the other, as *Garcias*, and *Scaliger* upon *Garcias* noteth it. Camfire doth coole the heate of the liver and backe, and all hot inflammations and distempers of heate in any place of the body, easing the paines in the head, and restraining fluxes, either of blood out of the head and nostrils, being applyed to the forehead with the juyce of Houseleeke or with Plantaine water, and some Nettle seed, or the fluxe of sperme in man or woman, using it to the reines or privy parts, and extinguisheth Venery, or the lust of the body: It is a preserver from putrefaction, and therefore is put into divers compositions and antidotes

dotes to resist venome, poysons, and infection of the plague or other diseases: it is good in wounds and ulcers to restraine the heate, and is of much use with women that desire to preserve their beauty, by adding a luster to the skinne.

## CHAP. XIX.

### *Caranha.* The Gumme *Caranha.*

CAranha, *Caranna*, or *Caragna*, is a gumme brought from the West Indiēs, whose tree is not described by any that have written of it, but is a soft kind of Gum, wrapped up in leaves that one peece should not sticke unto another, for it is very cleaving, and is of a darke or muddy greenish colour, having somewhat a sharpe piersing sent: but there is another sort as *Monardus* saith, that is as cleere as Christall, which I never saw: It is a most especiall and speedy helpe, when *Tacamahaca* could not as *Monardus* saith be had, for all cold aches, and paines in the nerves and joynts, and the swellings and paines therin, the defluxions also of humours on them, or on the eyes, or on any other part to be laid on the temples or behind the eares: it is also used as well as *Tacamahaca* for the toothach to be laid on the temples like Masticke.

## CHAP. XX.

### *Cardamomum.* Cardamomes.

THere hath beene formerly much controversie concerning Cardamomes, whether we have either that of the *Grecians*, or those of the *Arabians*, some supposing we have neither, and that the Cardamomes we daily use, agree with neither of all their descriptions. *Theophrastus*, *Dioscorides* and *Galen*, among the auncient Greekes, and *Pliny* among the Latines mentioning but one sort, and the *Arabians* two,

*Meliguette sive Cardamomum maximum et Grana Paradisi.*

*Cardamomum majus vulgare.*
The greater sort of Cardamomes.

*Cardamomum medium & minimum.*
The two smallest sorts of Cardamomes.

a greater

a greater and a lesser, but *Fuchsius* and *Ruellius* thought the *Capsicum* or *Siliquastrum*, our red Indian Pepper in long horned huskes, was the *Arabians Cardamomum minus*, which *Matthiolus* disproveth as improbable, yea impossible, the difference both in forme and property so farre disabling it, and some supposing the *Melegueta* or *grana Paradisi*, which we call usually graines, or Ginney graines, to be the *Grecians Cardamomum*, and the Monkes that commented upon *Mesues*, tooke the said *Melegueta* to be the lesser Cardamomes of *Serapio*, all which and many other opinions may now be buryed, and we better resolved that *Dioscorides* his *Cardamomum*, not onely agreeth with *Galens*, whereof divers made a doubt, because *Dioscorides* maketh his to be sharpe in taste, and fierce in sent, piersing the senses, and *Galen* pleasant, and not so sharpe or hot as Cresses: for *Galen* no doubt understood the same of *Dioscorides*, when in a receipt that he had from *Pamphilus*, 7. *de comp. med. secund. locos. c.* 3. he appointeth *Cardamomum delibratum*; Cardamomes that were husked to be taken, as also in *secundo antidot*, *Zeno* casteth away the huskes, and in the *Theriaca* of *Damocrates* in verse, Cardamomes in huskes are named, and *Dioscorides* mentioneth not any huskes, or other forme thereof, because it was so familiarly knowne in his time, but that it was not easie to be broken, which the huske being tough doe declare: but it also agreeth with those we use in our shoppes, and with that which *Pliny* mentioneth, who as I said in the Chapter of *Amomum*, saith *Cardamomum* is like thereunto, that is to *Amomum*, both in name and growth, but that the seed is longer meaning the huske with the seed in it, as it is used to be taken by him and others in many things. And that of *Dioscorides* agreeing with that we use in our shops, cannot be any other also then that of the *Arabians*, usually brought to all these Christian parts, from the East Indies as *Garcias* confesseth, and especially the lesser, which as *Garcias* saith is the better, although as he saith, they be both of one kinde, differing in bignesse, the bigger sort being somewhat longer and rounder, and the small shorter and not so great, but as it were three square. Now as concerning *Garcias* his opinion that the *Arabians Sacolaa quibir*, and *ceguer Cardamomum majus & minus* was not knowne to the ancient Grecians or Latines, assuredly he was mistaken therein, for the notes and markes of *Dioscorides* his *Cardamomum* doe in all things agree both with ours in use, brought from India, and that of *Pliny* as I said before, so that now seeing both Greekes, *Arabians*, and Latines are thus reconciled together, there needeth not rest any further doubt hereof to use our Cardamomes in any of their receipts: but the *Melegueta* or *Grana Paridisi*, which is in forme like to a Figge, and full of reddish seed, although it be good and safe spice to be used, yet can it not be the *Cardamomum majus*, as divers have formerly taken it, and to this day is so supposed by many, but as *Garcias* saith, it may be the *Combasbogue* of *Avicen*, the greater and lesser Cardamomes differ not in kind but in greatnesse, the one from the other, and is called as *Garcias* saith by the Merchants of *Malavar Etrimelli*, by them of *Zeilan Ensal*, in both which places it groweth plentifully as *Garcias* saith, in *Bengala* and *Surrat Hil*, and of some *Elachi*, but generally of the common people *Dore*, in all those places: The Vertues whereof are these: it is hot and dry in the third degree: it breaketh the stone, provoketh urine when it is stopped or passeth with paine: it resisteth poyson and the sting of the Scorpion, or other venemous creatures, and killeth the birth if they be perfumed therewith: it is good against the falling sicknesse, the cough, the broad wormes, and the torments or griping paines in the guts, or bowels, and expelleth winde powerfully, both from the stomacke and entralls, easeth those that by falls or beatings are bruised and broken, those that have loose and weake sinewes, and the paine of the Sciatica or hip gout, and used with vinegar it is good against scabbes: it is used in many of our compositions, cordialls, Antidotes and others: the Indians as *Garcias* saith, put this to the composition of their *Betre* leaves, which they continually chew in their mouthes.

## CHAP. XXI.

### *Caryophylli.* Cloves.

ALthough Cloves and Nutmegs, and some other spices and drogues were not knowne to *Dioscorides*, *Galen*, and the other auncient Greekes, for *Serapio* in citing *Galens* authority for Cloves, is either false or mistaken, for *Paulus Æginetа* a later Greeke writer doth not mention it, neither yet doe the Latines, or *Pliny* in his time (for his *Caryophyllon*, or *Garyophyllon lib.* 12. *c.* 7. is a round graine like Pepper, as is shewed before with the *Amomum*, but greater and more brittle, and was taken by some in these dayes to be *Amomum*, and by others *Carpobalsamum*) yet were they knowne to the later Greeke: by meanes of the *Arabian* Authours, who have brought a more ample and exact knowledge of the Indian commodities, and of many other things, then were formerly knowne, so that now what by the *Portugals* travels, the *Dutch* and ours by sea unto those parts; the tree hath beene well observed, to be great and tall, covered with an ash-coloured barke, the younger branches being more white, having leaves growing by couples one against another, somewhat long and narrow like unto the Bay tree that beareth narrow leaves, with a middle rib, and sundry veines running there through, each of them standing on a long footestalke, the ends of the branches are divided into many small browne sprigs, whereon grow the flowers on the toppes of the Cloves themselves, which are white at the first, with their sprigges, greene afterward, and lastly reddish before they be beaten off from the tree, and being dryed before they be put up grow blackish as we see them, having foure small toppes at the heads of them, and a small round head, in the middle of them, the flower it selfe standing betweene those, consisteth of foure small leaves like unto a Cherry blossome, but of an excellent blew colour, as it is confidently reported with three white veines in every leafe, and divers purplish threds in the middle of a more dainty fine sent then the Clove it selfe, which is a small slender fruite, almost like a small nayle, and therefore called *Clavus* by many, and from thence the *Dutch* call them *Naegelen*, being of a hot quicke and sharpe taste, which are first ripe and gathered, but those that doe abide longer on the trees, doe grow somewhat thicker and greater, and are not of halfe the others goodnesse, being called by most *Fusses*, yet some call the stalkes of the Cloves *Fustes*, and grow of their owne falling, and are not grafted: Hereout likewise commeth a certaine darke red gum, and are found usually put together; These grow chiefly in the *Malucca* Islands, where they gather them twise every yeare, that is, in *Iune* and *December*, the leafe, barke and wood, being nothing so hot in taste as the Clove: they grow also in *Amboyna*, where they grow well, and beare plentifully, being there planted

*Caryophyllorum effigies spuria.*
A false figure of the Clove tree.

*Caryophyllorum vera genuina effigie.*
A branch of the Clove tree with the fruite truely expressed.

planted by the *Dutch*, in other places of the Indies more scarsely and lesse fruitefull then there, which are called generally by the Indians *Calefur*, and by those of the *Maluccas*, and in some other places *Chanque*. The properties of Cloves are many and excellent, being hot and dry in the third degree, yet some say the second, and of much use both in meate and medicine, comforting the head and the heart, and strengthening the liver, the stomacke, and all the inward parts that want heate, helping digestion, to breake winde, and to provoke urine: The oyle chymically drawne is much used for the tooth-ache, and to stop hollow aking teeth, as also to be put into perfumes for gloves, leather and the like, the Cloves themselves for their excellent sent, serving as a speciall part in all sweet powthers, sweet waters, perfuming pots, &c. *Garcias* saith that the *Portugall* women distill the Cloves while they are fresh, which make a most sweet and delicate water, no lesse usefull for sent, then profitable for all the passions of the heart, the weakenesse of the stomacke, &c. and with the pouther of Cloves applyed to the forehead helpe the head ach comming of cold, as also by eating them procure a sweet breath: Some as he saith procure sweating to those that have the *French* disease, by giving Cloves, Nutmegs, Mace, long and blacke Pepper, but this hath no use with us. *Christophorus a Costa* saith that they binde the belly, and sharpen the eye sight, clensing them and taking away filmes, or clouds that darken it, if their water be dropped into them, and that foure drammes of the pouther of Cloves taken in milke, will procure and stirre up venery or bodily lust.

## CHAP. XXII.

*China radix officinarum.* The roote China.

THe rootē called China, is like to the rootē of a great reed, somē flattish, others round, not smooth, but bunched or knotty, reddish for the most part on the outside, and whitish, or sometimes a little reddish on the inside, the best is solid or firme, and somewhat weighty, fresh and not worme eaten, and without any taste, but as it were drying: it groweth up with many prickely branches, of a reasonable great bignesse, like unto *Sarsa parilla*, or the prickely Bindeweed, winding it selfe about trees, and hath divers leaves growing on them like unto broad Plantaine leaves, the rootes grow sometimes many together, and may be eaten while they are fresh, and so the Indians doe with their meate, as we doe Carrets or Turneps: It not onely groweth in *China*, but in *Malabar*, *Cochin*, *Cranganor*, *Tanor*, and other places there, and is called *Lampatan* by the *Chinoses*, and *Chophchina* by the *Arabians* and *Persians*. The properties whereof are many, and of great use with us in divers cases: it was at the first knowledge thereof to the Christians, and others that dwelt in India, chiefly used for dyet drinkes in *Lua Venerea*, the *French* disease, but since it is found profitable in agues, whether *quotidian* or *intermittant*, or pestilentiall, and also hecticks and consumptions,

*China radix officinarum.* The true China roote.

*Pseudochina.* Bastard China.

sumptions, to rectifie the evill disposition of the liver, the inveterate paines in the head and stomacke, and strengtheneth it, and to dry up the defluxions of rheumes, to helpe the jaundise and the burstings in children or others by drying up the humour, which is the cause thereof: it helpeth also the palsie, and all the other diseases of the joynts and bladder, the gout and Sciatica, and the nodes also, and ulcers of the yard, and is good in all cold and melancholicke griefes, some take it to be a great incendiary to lust: the manner of taking it is divers, for some boyle it being sliced thinne, and steeped for a good while in water onely, and some adde wine thereto, and some boyle it in the broth with a chicken, tyed up in a linnen cloath, and to take from a quarter to halfe an ounce or more at a time, as the quantity of drinke or broth you will provide, or as the party can beare. We have had a kinde of roote brought us from the West Indies in forme somewhat like unto this true, but harder, redder, and more knotty, which some called bastard China, and was not used by any that I know, *Monardus* saith that the true was planted in the West Indies, and brought from thence very fresh into *Spaine*. *Pseudochina*

## CHAP. XXIII.

### *Cinamomum, Canella & Cassia.* Cinamon and Cassia.

I Know that divers learned men are of opinion that Cinamon, Canell, and Cassia are three distinct things, differing each from other, and that we have no true Cinamon brought to us (which controversie is too long to insert in this place) but that which we usually have, is as they call it Canell or Cassia, and not Cinamon, yet *Garcias* sheweth that the *Chinesse* and *Arabian* Merchants, and others were the cause of this plurality of names given to one thing, and of the fables that are extant in *Herodotus* and others of it, and other things; and that the diversity of goodnesse, either thicknesse or blacknesse, or other outward forme, or quicke and sharpe taste, or dull and lesse sapid, or the place of growing made the severall sorts that passe under severall names, both now and heretofore with the ancient writers; for if one would be curious now to search among the great store of Cinamon, that commeth from the East Indies yearely unto us, as *Clusius* and others have done, he might finde as much diversitie both in goodnesse and colour as he or any other did at one time or another: for being the barke of a tree, the goodnesse followeth usually, either the place of growth, one being better then another, or the oldnesse of the trees, the younger being the thinner and still having the quicker taste and the fresher colour, all the *Arabians* as *Garcias* saith doe generally call it, be it of what sort soever, *Querfaa*, or *Querfe* (or *Kerpha*, which in *Avicen* is a worse sort, as *Scaliger* noteth, in *Zeilan Cuards*, by the *Persians Darsini*, that is, the wood of *Sina*, which the *Portugalls* first corruptly called China, and from thence is the name China used by all others: but whereas *Garcias* saith that the name of *Cinamomum* was given by those of *Ormus* that bought it of the *Chineses*, as though it were *China Amomum*. *Scaliger* in his

*Cinamomi folium & bacillum.*

*Lobel* his Cassia lignea.

his notēs on him saith nothing could be morē unfitly or foolishly spoken, for China as is shēwēd, is but the corrupt pronuntiation of the *Portugalls*, and what affinity saith he hath *Amomum* wih *Cassia*, *Cinamomum* being so ancient a word, that we finde it in sundry places in the Bible, by the Hebrewes named *Kinnamon*, as *Exod.* 30. 23. *Cantic.* 4.14. and *Prov.* 7.17. But herein I thinke *Scaliger* is too quicke and selfe conceited, for *Garcias* sayings notwithstanding may hold good, the *Sinenses* or *Chineses*, having beene anciently the greatest Merchants for those parts as *Garcias* sheweth. And although it were rare in *Europe*, at a thousand *denarios* (or *drachmas*, for I thinke them all one) for a pound as *Pliny* saith, and chiefely kept by Princes as part of their trēasury, yet we read in the Scripture that the *Ishmaelites*, *Midianites* and others, were the Merchants of spicery for those parts, whereof Cinamon in those three places aforenamed was one no doubt. But *Galen* his description of the Cinamon tree (which was wholly brought in a chest to *Rome*, of foure cubits and a halfe in length, having some sixe or seven stemmes, more or lesse, rising from a roote with sundry branches thereon, whose youngest and tendereſt, as he saith, were the quickest and chiefest to be used, the longest of them being not above halfe a foote long, of a colour saith he, as if unto milke some blacke colour, and a little blew were mixed together) so differing as it may seeme from that we now so call, that it hath caused many to say, that the true Cinamon is utterly lost, even as *Opobalsamum* and *Amomum* was thought to be, and peradventure all alike, for if it be granted that wee have Cassia, as many doe, then assuredly true Cinamon will not be farre to seeke, for *Galen* in the place before cited, in the end of the said narration of Cinamon hath these words, *Universa autem Cinamomi natura, similis est quodammodo optima Cassiæ*, that is Cinamon is in some sort like unto Cassia: And therefore all that *Aldinus* hath said, seeming to himselfe to have said something materiall, is little or nothing to any purpose. *Monardus* also in the place before cited, mentioneth a West Indian Cinamon which is onely a blackish purple flat kind of fruite, like a peece of silver, the *Spaniards* call a ryall of eight, or a *Dutch* Dollar, but higher in the middle and of that thickenesse on the edges, and rough on the outside and tasting like Cinamon, the pouther being used in meates and brothes, the tree being of a meane size, with leaves like Bayes, and evergreene, the leaves tasting a little like the fruit, but no part of the tree else having any taste. The Cinamon tree is described by *Garcias* to be as great as the Ollive tree or somewhat lesse, with many straight branches without knots, covered with a double barke like the Corke, whose inner rinde is the Cinamon, and is so barked every third yeare, and being cut into long peeces, as if it were the bark of the whole tree, is cast on the ground, where in drying it is rouled together, as we see it, & is better or worse, blacker or better coloured, as is said before, or by the greater or lesser heat of the Sun, somewhat more changed: the leaves are of a fresh greene colour, and like unto those of the Citron tree (and not like the Flower-deluce leafe, as some have fabulously written) or as *Christophorus a Costa* saith with three ribs, but *Garcias* disavoweth it: the flowers are white, and the fruite blacke and round like Hasell Nuts or small Ollives, and not like Acornes, but the best groweth in *Zeilan* with leaves like Willowes rather then Bayes, with spreading branches and fruite like Bay berryes, whereof they make an oyle. Now concerning Cassia, whether it differ in *genere* or *specie*,

*Cinamomum Americanum.*

*ſpetie* from Cinamon, called Canell in ſome countryes reſteth to be ſhewed: both *Garcias*, and *Monardus* ſpeaking of the Weſt Indian commodites in the 25. Chapter of his Booke, ſay that the tree is but one that beareth both theſe ſorts, and that the variety of places maketh the difference onely: but becauſe *Dioſcorides* and the other auncient Authours have not onely made them as it were two kindes, but appointed them both to be put into one medicine, eſpecially *Mithridatum*, and *Theriaca Andromachi*, and in the holy annoynting oyle in *Exodus*, we will a little more exactly ſcan the matter, for although we finde that all the Caſſia or *Caſia lignea*, that commeth to us or was formerly knowne is the barke of a tree, and either rouled together like Cinamon, or not rouled but in ſmall or great ſmooth peeces, and therefore may well be perceived to be a ſort of Cinamon, yet the taſte being glutinous leſſe ſharpe and quicke, and more ſtipticke then Cinamon, argueth it to be the barke of another ſort of tree, although of the ſame kinde, and peradventure may be that kinde whereof I entreated in the 64. Chapter of the laſt Claſſis of trees, which I there call *Laurus Americana*. And although that which we have alwayes uſed come to us from the Eaſt Indies, yet that letteth not but that it may grow alſo in the Weſt. And however both *Virgill* and *Pliny* call that herbe Caſſia, which was ſowne or planted in Gardens, as well for Garlands as to feed Bees with their flowers, as hath beene ſhewed before, yet they both doe mention a tree Caſſia. *Virgill ſecundo Georgicorum* underſtandeth this tree Caſſia, as it is likely in theſe words, *Nec Caſia liquidi corrumpitur uſus Olivi*. And *Pliny lib. 12. c. 29.* in theſe words, Caſſia that groweth where Cinamon doth, is a ſhrub of three cubits high, but on the hills whoſe thicke branches have their barke more like unto leather, which muſt be emptied or hollowed in a contrary manner, unto that of Cinamon, for being cut into ſtickes of two cubits long, they are ſowed into freſh beaſts skinnes, that the wormes may eate out the wood, and leave the barke whole, by reaſon of the ſharpeneſſe and bitterneſſe: the three ſorts of colour therein ſheweth their goodneſſe, that which is white for a foote high next to the ground is the worſt; the next thereunto for halfe a foote is reddiſh, which is next in goodneſſe, from thence upward which is blackiſh, and the beſt, and is to be choſen freſh, of a milde ſent and of a very ſharpe taſte rather then biting, of a purpliſh colour, light in weight, and with a ſhort pipe, not eaſily broken: Thus farre *Pliny*, which for the moſt part he borroweth out of *Theophraſtus*, *lib. 9. c. 5.* where he ſaith Caſſia is a ſhrub, like the *Salix Amerina*, which becauſe it is hard to be barked, men have invented the way by beaſts skinnes, as is before ſaid out of *Pliny*: The barke being onely to be uſed, which I rather thinke to be a fable of report then truth: the reſt that followeth in *Pliny*, is out of *Theophraſtus* in his narration of Cinamon, where *Theophraſtus* maketh five ſorts, the loweſt the worſt, becauſe it had leaſt barke, and the uppermoſt the thickeſt as the beſt (which how likely it is that the barke of any ſhrub or tree, ſhould be thinneſt below, and thickeſt above, when as the contrary is alwayes ſeene in all ſorts of trees, with us and others too I thinke) *Galen* in acknowledging Cinamon to be a tree with ſundry branches, ſaith he hath obſerved not onely the branches of Cinamon to be converted, and very like thoſe of Caſſia, but thoſe of Caſſia alſo to be in all parts like Cinamon, and that which bore the name of *Zigi*, was ſo like to Cinamon, that divers ſold it for Cinamon, when it was but true Caſſia. And againe ſaith that the *Junior Andromachus* mentioneth a kind of thicke groſſe Caſſia, which he called *Caſſa fiſtula*, becauſe it was rouled together like a Pipe. And therefore *Serapio*, *Avicen*, and *Meſues*, in their compoſitions appointing *Caſſia fiſtula* to be uſed, which as *Matthiolus* doubteth whether it were their owne or their tranſcribers fault, this Caſſia is not to be taken, but that which hath hard canes, and a blacke pulpe, more fitly termed *Caſſia ſolutiva* or *nigra*, and which many yet doe uſe in ſtead hereof; but as *Leovicenus* ſaith, their errour is too great to be excuſed, that appoint the ſhels of that *Caſſia ſolutiva*, to be uſed to move womens courſes, to helpe their hard travels in childbirth, and to expell the ſecondine or afterbirth. By all which that is now ſaid, you may ſee plainely that Caſſia differeth not much from Cinamon, and yet that is differing from it. *Lobel* giveth us the figure of another ſort of Caſſia, which was as thick as ones thumb rugged & in taſte like unto the thick courſer ſort of Cinamon. Having thus ſhewed you the whole deſcription of theſe things, and the various paſſages of them, let me alſo give you the Vertues which are theſe. Cinamon is hot and dry in the ſecond degree, of very ſubtle parts, and very aromaticall, it is very cordiall, comforting the heart and ſtrengthening a weake ſtomach, easing the paines of the winde chollicke, eſpecially the diſtilled water of it, the ſtopping of the urine and wa of abounding courſes, it cauſeth a good colour in the face, and a good ſweete breath, and reſiſteth the m in all venemous creatures, it is much uſed alſo in laskes to binde the body, the deſtilled water is moſt eff theſe griefes, but the chymicall oyle thereof is much more hot and pierſing.

*Xylocaſſia Lob.*

I thinke it not amiſſe in this place to make mention of ſome other barkes of trees and rolls in long roules, brought both out of the Eaſt and Weſt Indies: The firſt whereof called white Cinamon, and more tough then white both within and without, turned together like unto Cinamon, is thin in taſte and ſent, being Cinamon, the taſte is ſomewhat hot, and reſemble Cloves rather then Cinamon, had ſmelt and taſted weake very aromaticall, yet leſſe in each quality, then Cloves, ſo that one would thin Cloves.

*Canella alba.*

Another ſort rouled like Cinamon, not very thicke, which the *Dutch* uſius ſaid *lib. Exot. 4. c. 2.* brought out of India, comming from the *Moluccas* and *Iava*, and which he teth whether it be not the Caſſia of the ancients, or ſome of the ſorts whereof *Dioſcorides* maketh menti ſome of it was whitiſh on the outſide, and ſome more browne, like the worſer ſort of Cinamon, of no up ant taſte, yet not ſo ſharpe as Cinamon, and having a little clamminеſſe in the chewing, the people uſe pouther in their meates.

*An Caſſia veterum Cluſio.*

Another *Cluſius* maketh mention of in the ſame Boo and third Chapter, which was a foote long or more, and three inches in circuite at the lower end, and tw iches at the top, had the outer barke thinner, then the inner, for it had two, and was very rugged, full of ckes and with ſome holes, and ſometimes two at a place in a certaine order, all the length thereof but ſet a wart thereon, which ſeemed to be the places where the leaves grew, both the barkes were of an e cellen weete and aromaticall ſent and quicke taſte eſpecially the outermoſt.

*Canella alba ex arbore.*

*Monardus* ſpeaketh of a Canell of e new world, growing in *Quito*: the trees ſaith he that beareth this Cinamon are of a meane bigneſſe and ver greene (as moſt of the Indian trees are) the leaves are like to thoſe of the Bay tree, the fruite is like unto ittle hat, as broad as a Doller, or *Spaniſh* peece of eight, and ſometimes greater, the brimmes being of their thickeneſſe, and both inſide and outſide, of a darke purpliſh colour, ſmooth within and rugged

*Canella novi orbis.*

rugged without, the toppe being higher, and had a ſtalke whereby it did hang, and was faſtened to the tree, this fruit was in taſte very like unto that of Cinamon, with ſome aſtriction joyned thereto, and the pouther of them ſtrewed on their viands, was uſed for Cinamon, the barke of the tree was thicke, and had no taſte or ſmell of Cinamon, the fruite onely being of uſe, and good to comfort the heart and ſtomacke, diſſolve winde, mend a ſtinking breath, procureth a good colour in the face, and to provoke womens courſes.

## CHAP. XXIV.

*Coculus Indus.* Cocculus Indi.

THeſe berryes or round ſeed the *Italians* call *Cocco di Levante*, and the *French* accordingly, they are of a blackiſh aſhcolour on the outſide, having a white kernell within them of an hot taſte, drawing water into the mouth, and as it ſeemeth grow many together like Ivy berryes, yet each by it ſelfe on a ſtalke, ſome thinking them to grow upon a kinde of Nightſhade, others on a kinde of Tithymall, or Spurge. *Cæſalpinus* calleth them *Galla orientalis*, others *Baccæ orientales*. They are wholly ſpent either to make baites to catch fiſh, with other things for that purpoſe, or the pouther uſed to kill lice and vermine in childrens heads.

*Coculus Indus. Coculus Indi.*

## CHAP. XXV.

*Coſtus. Coſtus.*

THeſe hither parts of *Aſia minor*, and *Africa*, beſides all *Europe* as it is ſuppoſed for many ages of theſe later times, have wanted not onely the uſe, but the knowledge of the true *Coſtus*, of any of the three ſorts, that *Dioſcorides* mentioneth, eſpecially *Europe*, and it was the *Arabians* that firſt brought in the deviſion thereof into ſweete and bitter, when as neither *Dioſcorides* nor *Pliny* make any men-

*Coſtus Indicus Cluſij.*

*Coſti diverſæ ſpecies.*
Divers ſorts of Coſtes exhibited for Coſtus.

tion

tion of bitterneſſe, although *Galen* doth, but of ſweeteneſſe in taſte, none of them all but *Actuarius* onely, who is one of the later Greeke Writers: *Garcias* to excuſe the *Arabians*, of this their diviſion of *Coſtus* into *dulcis* and *Amarus* ſaith, that it might be that while the *Coſtus* was freſh it is white, and hath no bitterneſſe in it, but growing old, it groweth blacke and gathereth ſome bitterneſſe to it, by the decaying, but the Apothecaries ſhops, eſpecially in *Europe*, ſhew two ſorts, farre differing the one from the other, both in forme and ſubſtance. Of late dayes indeed they have beene more carefull and induſtrious to know the right, and to ſearch for it and uſe it, the *Portugals* therefore from the Indies brought in one ſort, which as *Garcias* ſaith was onely uſed there and no other, but as *Clusius* noteth it in his *Scholia* thereon, this being a ferulous ſpongy ſtalke, with the toppe onely of the roote to it, differeth from thoſe of *Dioſcorides* and *Pliny*, the one intimating it to be a roote, by ſaying it was uſed to be adulterated or falſefyed by obtruding the rootes of *Helemium Comagenium* for it, which were neither very hot, nor very ſweete in ſent, and *Pliny* ſaying plainely it is a roote: but there hath beene very lately brought unto us a ſort of roote called *Coſtus*, and taken by many to be the *Syriacus*, yet ſome thinke it to be the *Arabicus* of *Dioſcorides*, being ſomewhat yellowiſh on the outſide, and white within, ſmelling and taſting ſomewhat ſweete like Orris, which therefore I judge cannot be right, which as *Pliny* ſaith is very hot in taſte and very ſweete in ſent, and *Galen* giveth it ſuch a degree of heate, beſides the bitterneſſe, that it will exulcerate the skinne: many therefore have ſubſtituted *Zedoaria* in the want thereof, which is the beſt ſubſtitution that can be, agreeing both in forme and degree, moſt of all thereunto; and therefore divers have contended that it was the true *Coſtus*, but in regard *Zedoaria* hath more bitterneſſe and leſſe ſweeteneſſe therein, it cannot be *Coſtus*, yet may be admitted as the ſubſtitute thereof, but *omne ſimile non eſt idem*: Some againe hold Angelica to be the blacke or Indian *Coſtus*, but being a homebred plant ſo, it cannot be, and beſides hath no ſuch bitterneſſe and ſharpeneſſe therein, as *Galen* giveth to *Coſtus*. The *Arabians* call it *Coſt* or *Caſt*, thoſe of *Surrat Uplot*, and in *Malacca* where they much uſe it *Pucho*. The Vertues hereof as *Dioſcorides* hath ſet them downe of the true *Coſtus*, (which as is beforeſaid is doubtfull whether we have or no) are theſe. It provoketh urine and womens courſes, and helpeth the diſeaſes of the mother, as well by bathing as fuming: two ounces thereof being drunke, helpeth the biting of Vipers, and is good againſt the paines of the breſt, convulſions, or the windy ſtitches, ſwellings or puffings in the ſtomacke, ſides or body, being taken with wormewood in wine, and being taken with ſweet wine it provoketh Venery, it killeth the broad wormes of the belly: it is uſed with oyle to annoynt the body, before the cold fit of agues to warme it, and thereby to expell it, as alſo againſt the weakeneſſe of the ſinewes, and the hip-goute, and amendeth the diſcolouring or blemiſhes of the skinne and face, uſing it with hony and water, and as *Galen* addeth by reaſon of the light bitterneſſe, and much ſharpeneſſe and heate, it will exulcerate.

## CHAP. XXVI.

### *Cubebæ.* Cubebs.

CVbebs are ſmall berries ſomewhat ſweete, no bigger then Pepper cornes, but more rugged or creſted not ſo blacke nor ſolid, being either hollow or with a kernell within it, of a hot glowing taſte, not fierce as Pepper, and having each a ſmall ſhort ſtalke at them like a taile, and therein very like to a kind of Pepper, was for a while wont to be brought to us, which the *Portugals* called *Pimenta del rabo*, *Piper caudatum*, Pepper with a taile, and was forbidden by the King of *Portugall* to be brought any more leaſt it ſhould ſpoyle the ſale of the other Pepper: this ſaith *Garcias* groweth on trees leſſe then Apple trees, with leaves thereon narrower then thoſe of Pepper running on trees like Ivy, or rather like Pepper, but not like unto *Ruſcus*, called *Myrtus ſylveſtris*, as *Matthiolus Silvaticus* thought, as *Serapio* ſet it downe but falſely: the flower is ſweete, and the fruite groweth cluſtring together, yet not in bunches as Grapes, but more ſeparate. *Cæſalpinus* tooke them to be *Amomum*, many others out of *Avicen* and other Authours, tooke them to be the *Carpeſium* of *Galen*, and ſome to be the ſeed of *Vitex*, or *Agnus Caſtus*. The *Arabians* call them *Quabebe*, and *Quabebe chini*, but in *Java* where they grow plentifully enough, and are there of ſo great account, that it is ſaid, they boyle them in water before they part with them, fearing they might be ſowne and grow in ſome other place and uſe them much to ſtirre up Venery, and to warme and ſtrengthen the ſtomacke overcome with flegme or winde, and doe purge the breſt of thicke tough humours, helpe the ſpleene, diſſolve wind and are very profitable for the cold griefes of the wombe: being long chewed with Maſticke they draw much flegme and rheume from the head, and ſtrengthen the braine or memory.

*Cubebæ.* Cubebs.

## CHAP. XXVII.

### *Curcuma.* Turmericke.

IT is very likely that Turmericke is *Dioſcorides* his *Cyperus Indicus*, which he ſaith hath a roote like Ginger, giving a yellow colour like Saffron, being bitter in taſte, and a preſent helpe to take away haire: all which notes agree notably hereunto, the roote being much liker to Ginger then unto any kinde of Cyperus, and therefore we may marveile the more why *Dioſcorides* ſhould referre it to Cyperus, unleſſe he had underſtood of thoſe that had ſeene it, that it did grow like unto a Cyperus, and is very yellow both within and without, bitter in taſte, and may ſerve for the haire, as it is ſpecified, although peradventure the force is halfe loſt by the long carriage, but this is not the *Curcuma* of *Serapio* or *Avicen*, as *Matthiolus*

*thiolus* hath well noted, which is no other then the greater *Celandine*, whose roote is yellow, and therefore the Apothecaries in former times tooke it for *Curcuma*, and put it into the composition called *Diacurcuma*. *Garcias* and *Christophorus a Costa* call it *Crocus Indicus*, and say that the Indians call it *Alad*, and *Manjale*, the *Arabians Habet* and *Curcum*, the *Turkes* and *Persians*, *Saroth*, and *Darsard*, that is *lignum luteum*: it beareth larger and thinner leaves then Miller, of a paler greene colour, a stalke full of leaves, compassing one another to the toppe: the roote is slender and yellow, neere unto the forme of Ginger, nothing so bitter, being fresh by reason of the moisture in it, as when it is dry. It is of great use with many for the yellow jaundise, either the pouther or the decoction being taken, for it doth open the obstructions of the gall and other parts, it is of very good use in old and inveterate griefes and sickenesses, and an evill disposition of the body called *Cachexia*, and is very profitable against the dropsie: it is much used to colour divers small workes of wood instead of Saffron, the Indians use it much both to season and colour their meates and brothes, because it is to be had better cheape than Saffron, and as *Garcias* saith is put into those medicines are made for the eyes, and for the itch, if some juyce of Orrenges, and the oyle of the Cocar or Indian nut be mixed with it.

*Curcuma.* Turmericke.

## CHAP. XXVIII.

*Folium Indum sive Malabathrum.* *Folium Indum* or Indian leafe.

THat *Dioscorides* and the other Auncient writers had divers false relations of drugges and other things brought unto them; which they have set downe in their writings, may be well discerned by this called *Malabathrum*, which they said as they were informed, did grow in ponds and watery places swimming thereon as the *Lens palustris*, Duckes meate doth: for it is well knowne now and so set downe by *Garcias ab Orta*, and other the later writers, that they are the leaves of a great tree growing on land farre from waters in *Cambaia*, as well as in divers other places of the East Indies, and called *Tamalapatra* by them, which by corruption was first changed into the Greekes ταμαλάδαθρα and then into *Malabathrum* but by the *Arabians Cadegi Indi*, that is, *Folium Indum*, and are faire broad leaves with three ribbes onely in them, a little pointed at the ends, which have beene brought unto us, although very sparingly, and among them some yet abiding on their branches, two usually at a joynt tasting somewhat hot like unto Bay leaves, the barke of the branches also tasting like unto them; among these leaves likewise have beene found sometimes a small fruite like unto an Ackorne in the cup, which it is most probable is the fruite of the tree, and gathered with the leaves: but hath beene formerly supposed by some to be the fruite of the Cinamon tree, and by others obtruded for *Carpobalsamum*: Some have taken these to be the leaves of the Clove tree, but they are therein much deceived, for they have not those three eminent ribs in them that these have, which is a note to distinguish them from all other leaves almost, but some more probably have taken the leaves of the tree called *Betre* or *Tembul* to be *folium Indum*, because they have also some ribs in them, as *Marcus Oddo* doth in his examination of *Theriaca Andromachi*, but is also deceived, for the *Folium Indum* is not familiarly eaten as the *Tembul* or *Betre* leaves are: but whereas the substitute for these by our later Physitians appointment is the Maces which is the skinny covering of the inner shell of the Nutmegge, I find that *Avicen lib. 2. c. 259.* appointeth *Thalisafar* to be taken, which he describeth in the same Booke, and 687. Chapter, and by the most judicious is the *Macer* of the ancient Greeks, which they knew better then *Macis*, which was utterly unknowne to them, but as if they were one and the same thing, it hath beene generally so appointed, and is yet so taken to this day by most, but that *Macer* is not *Macis*: *Pliny* in his time sheweth plainely *lib. 12. c. 8.* saying *Macer* is the reddish barke of the roote of a great tree, called by the said name, comming from India, but there would

*Folium Indum sive Molabathrum.*
*Folium Indum* or Indian leafe.

need

need fewer substitutes by many in our medicines as well *Mithridatum* as others, if our Apothecaries would be most carefull and industrious to give instructions to the Merchants travailing into those parts, and out of those Authours that have written of them to give the *Arabian* or Indian name, whereby they might get the *genuine* drugges: for as *Garcias* saith there might easily be procured so much of this *Folium Indum*, as would serve all *Europe* if it were but sought after, and so I may say likewise for divers other things. The properties are to provoke urine powerfully, and is very beneficiall to the stomacke, warming and strengthening it, and maketh a sweet breath, it resisteth the force of venomes and poysons, and therefore is put into Antidotes and other compositions that are cordiall or stomachicall: it hath the properties of *Nardus*, but more effectuall being heated in Wine, it helpeth the inflammations and rednesse in the eyes being bathed therewith.

## CHAP. XXIX.

### *Galanga major & minor.* The greater and lesser *Galanga*.

THere are two sorts of *Galanga* a greater and a lesse: the greater is the weaker and duller in operation, and groweth in *Iava* and *Malabar*, to be two cubits high, having leaves foulding about the stalke at the lower end, being somewhat long and narrow, and pointed at the end somewhat like a speares head, of a sad greene colour on the upperside, and paler above: the flower is white but without any sent, the seed is small and neglected: the roote is somewhat great at the head like the reed (but *Clusius* taketh it to be more like unto a Flower de luce, then unto an Asphodill as *Acosta* compareth it, and that the plant may be a kind of *Iris*) of a blackish colour on the outside and whitish within, and use it familiarly in their meates as well as in their medicines: The lesser kind riseth not above a foote high, having leaves like the Mirtle, the roote is small and bunched, firme and somewhat tough, red both within and without, and smelleth a little sweet or aromaticall, it groweth in *China*, where it is called *Lavandou*, the greater being called in *Iava Lancuas* yet both of them are usually so called: it is more commonly planted by the roote as Ginger is, then of the seed, yet is both wayes encreased: There is great controversie among the later writers, concerning *Calamus*, *Acorus*, and *Galanga*, for some have held opinion, and is yet continued by many, that the *Galanga major*, is the true *Acorus* of the Ancients, which is an errour easily confuted if they that so thinke would but compare the notes of *Acorus* given by *Dioscorides* with this *Galanga*: others deny our *Calamus* in the Apothecaries shops, to be the true *Acorus*, which *Matthiolus*, *Clusius* and others have most evidently maintained, and as I have shewed before in the end of the first Classis of this Worke. Some also have set downe in their writings that *Galanga* is the roote of *Schænanthos*, but I may say *enarrasse est confutasse*. The lesser *Galanga* is both of more use, and of greater effect, and indeed is to be used onely in all the compositions wherein *Galanga* is appointed, and is very profitably given to cold and weake stomackes, and in the griping paines of the belly by winde, the diseases of the mother, and stop-

*Galanga major & minor.*

The Plant of Galanga as it groweth.

ping of urine, in which diſeaſe it hath a mervailous ſpeedy operation, to cleanſe the uritories from ſlimy flegme and ſtones gathered in them, or the paſſages in the necke of the yard, as alſo to waſte and conſume away fleſhy exreſſence in the necke of the bladder or yard: it alſo cauſeth a ſweet breath, being ſometimes chewed in the mouth, and helpeth a cold moiſt braine: it helpeth the trembling of the heart, and the wind chollicke.

## CHAP. XXX.

### *Gummi Elemi.* Gum *Elemni.*

THis Gum being not mentioned with the former becauſe we have not as yet attained the knowledge of the tree, from whence this Gum *Elemni* is taken; I reſerved for this place: for although ſome have taken it to be the liquour or gum that floweth out of the wild *Ethiopian* Ollive tree, yet it is moſt certaine it cannot be it, for it is ſaid that the gum of the Ollives will not burne like Roſſin, nor melt with the heate of fire, as the Gum *Elemni* will doe, which is a yellowiſh kinde of Gum, cleere and tranſparent, which being broken ſheweth more white and gummy within, quickely taking fire, and both burning and melting thereat, of a little quicke ſent and taſte. It is of eſpeciall uſe in all wounds and fractures of the head and skull, to be mixed with the Balſames and oyntments uſed for that purpoſe: it is alſo often uſed for the tooth ache, when the paines come by the defluxion of rheume into them, to lay a plaiſter thereof on the temples as they doe with Maſticke.

## CHAP. XXXI.

### *Guajacum ſive Lignum Sanctum. Lignum Vitæ.*

THe *Lignum vitæ* that groweth in ſome parts of the Indies, is much better then in others, yet is the wood of all, hard, firme, cloſe and heavy, ſo that it will ſincke in water more then Ebony and not ſwim, of an hot ſharpe and reſinous taſte, ſomewhat burning in the throate: the blacker or browner is better then the yellow, being in a manner all heart, the yellow being as it were but the ſappe: The tree groweth great with a reaſonable thicke greeniſh gummy barke, ſpread with ſundry armes and branches both great and ſmall, and on them winged leaves ſet by cou-

*Guajacum ſive Lignum ſanctum. Lignum Vitæ.*

*Guajaco Occidico ſimilis arbor.* A Weſt Indian tree like Guajacum.

ples one against another, which are but small thicke, hard, and almost round, with divers veines in them, abiding ever greene on the branches: at the joynts and ends of the branches come forth many flowers, standing in a tuft together, every one on a long footestalke consisting of sixe whitish yellow leaves, not very great with some threds in the middle, which afterwards turne into flat yellowish gristly fruite, of the fashion of the seed vessell of a *Thlaspi* or *Bursa pastoris*, that is, with two divisions, and in the one side a hard gristly seed, as hard as an horne almost, the other being for the most part empty, hanging downe together by their long footestalkes: it yeeldeth forth also a gumme or Rossin, of a darke colour, which will easily burne; it groweth in sundry places of the West Indies, where they call it *Guayacan*, and wee in Latine thereafter *Guajacum* by some *Lignum Sanctum*, and *Lignum Indicum*, and taken by some to be a kinde of Ebony, for the firmenesse and weightinesse, others a kind of Boxe. But as I have said heretofore in sundry places of this Worke, most of the Trees and Herbes that grow in the Indies are differing from those that grow in *Europe*.

*Guajaco Occiduo similis arbor.* A West Indian tree like Guajacum,

The branch of this tree I have here exhibited unto you, as *Lobel* hath set it forth before, not having had the like brought since his dayes that I know, which sheweth a more supine negligence in all our Sea men, then heretofore was usuall, which he hath described in this manner. The tree is great from whence this was taken, growing upright, whose barke was like unto that of the *Iudas* tree: the greene leafe, of the forme of a Pomecitron leafe, but thicke and smooth like unto the Bay, but larger and shorter, with sundry veines running therehrough, at the toppes of whose branches grow cods, of a leather like substance, and round forme in a manner flat like a peece of mony, in whose middle is contained flattish seed, like unto a Lentill, both for colour and forme, and bitterish taste.

*Palum Sanctum Indiæ Occiduæ.* A differing Indian Guajacum.

*Lobel* hath remembred this also in his *Adversaria* after this fashion: Divers have thought this to be a Palme like the last' or *Palus Sanctus*, a stake of such a holy tree, which yet is differing from it or *Guajacum*, howsoever it was so signified: for the tree is not very great like unto an Ash, but smaller, and the barke much like it in colour: the leaves were like Plaintaine leaves but thicker, fatter, smaller and shorter: the fruite was of the bignesse of a Wallnut, which served them to purge their bodies.

The diseases for which the usuall *Guajacum* is appointed, that is, both the wood, the barke, and gum, are sundry, helping all cold flegmaticke and windy humours, and although they are good, and with effect used for Epilepsies or the falling sicknesse, catarrhes, rheumes and cold destillations on the lungs, or other parts, conghes also and consumptions, the gout and all other joynt aches, and many other the like diseases, and to make the teeth white and firme, if they be often washed with the decoction thereof: yet was it first onely used for the *French* disease, as we and the *Spaniards* call it, the *Neapolitane* as the *French* call it, the *Spanish pippe* as the *Germans* call it, but as it is indeed the Indian contagion: for when *Christophorus Colonus*, commonly called *Columbus*, first opened the West Indies to the *Spaniards*, they companying with the Indian women, got this their familiar and naturall country disease from them, and brought it with them from *Santo Doningo*, being the first place the *Spaniards* possessed there, unto the King of *Spaines* campe, which was then at *Naples*, treating of a peace with the *French* King, in *Anno* 1493, bringing of the Natives with them, both men and women: The Physitions in those times not knowing this disease or the causes thereof were of divers opinions, some taking it to proceed from the corrupt vittailes that the souldiers were forced to eate, which bred melancholicke and adust blood, and humours, others to the conjunction of *Saturne* and *Mars*, and thereupon (not knowing it to be a new disease) they celled it by divers names, as the Leprosie, the running scabbe, the poxe and the like, referring it to some of the ancient knowne diseases, but all in vaine: the cure hereof by this wood, first was knowne from whence it first sprung: for a *Spaniard* being plagued with this disease, having an Indian that played the Leech, to be his servant, was cured thereof by drinking the decoction of the wood given him by the Indian, which cure was presently divulged, not onely to the rest of the *Spaniards* in the Indies, but in *Spaine* also, and so consequently to the whole world.

---

## CHAP. XXXII.

### *Hermodactylus.* Hermodactiles.

HErmodactiles are to be numbred among the unknowne Drugges, the shame of the Physitions in all ages and countries, who (although they put of the matter to the Apothecaries, and the Apothecaries to the Merchants that bring many sackes full into their Countries with other commodities, but they also take no further care to know what they are, or where or how they grow to declare it) should be skillfull in the knowledge of all Plants, and should give order that the unknowne might be made more manifest: but what doe I in so saying? runne my Barke on the Rockes and put her in danger of splitting. Divers of the later Writers, as well Greekes, as *Arabians* and Latines have made mention of the Hermodactile (although none of the Ancients) and have set downe the properties, well knowne by experience unto them, but no one hath ever declared either the place or manner of the growing thereof, but onely *Mesues*, who maketh a shew of description, which is almost as good as nothing, saying it is a roote of a mountaine herbe, whereof some are long like a finger, and are round, white both within and without, which every one may see by the sight, but that any should be long like a finger, is but rather his supposition from the name, then that he ever saw such indeed, and therefore divers have imagined diversly, some taking them to be the rootes of *Colchicum*, but they are dangerous if not deadly, besides the unlikenesse in forme, colour and substance: others take the *Dens Caninus* to be they, but they are more unlikely, for they are small and long, not thicke and short, as the Hermodactiles are: besides the quality no way agreeth, therewith *Matthiolus* first tooke the *Orchis Serapias*, called *Palma Christi*, the handed testicle to be they, because the word ἑρμοδακτυλος signifieth *Hermetis* or *Hermi dactylos*, *Hermes* fingers, and these rootes being like the fingers of ones hand, may well be so called, but having

having himselfe refused this errour, he fell into another as bad, takinh *Iris tuberosa*, the Velvet Flower de luce to be *Hermodactiles*, for the same cause that the rootes thereof runne out like fingers, which are such silly opinions that he may justly be beaten with his owne rod, that is, be taxed as he doth others, that in referring Plants doe not examine and well perpend each pert, rather then any one, before they determine of any thing: for Hermodactiles notwithstanding the Etimology of the word, have no shew or likenesse of fingers, but are small and somewhat flat, thicke and short white rooies, yet some are blackish, which are not good of the fashion almost of an heart, as it is painted on the Cardes, of substance firme, yet soft and easie to be cut or made into pouther, and of little or no taste, but drying, Master *Finch* our *London* Merchant was herein deceived. by taking the kernells of the *Tribulus aquaticus* Water Caltroppe, for Hermodactiles as I thinke, as I have shewed you in that Chapter: Yet I would we might be better informed of the truth herein, that if any can finde that bigger fruite, growing in any of the ponds or waters in our Land or elsewhere, by breaking the wooddy shells of them, and comparing the kernells with our Hermodactiles in shops, that so thereby we be fully assured of the truth hereof. It is most effectuall in purging flegmaticke, slimy, and watery humours from the joynts, and therefore conduceth to helpe the gout and other running joynt aches, it is also of much use with other things for dyet drinkes, that are made of *Guajacum*, *Sarsa* and the like, and to very good purpose.

## CHAP. XXXIII.

### *Lacca.* Gum Lake.

*Lacca* is no gumme distilling out of trees as other gummes doe, although it will melt with heat and burnē with fire as they will, but is a certaine peculiar matter, elaborate and wrought by certaine great winged Ants that breed in the ground, and sucking out from great trees of divers sorts but especially from that which is called *Mala Indica*, hereafter set downe, from which they take the substance of what they work, about the smaller branches (as Bees doe their hony and hony combes) and make this *Lacca*, which is a darke red substance, somewhat transparent, somewhat like, but harder then any Gumme, which being chewed will make the spittle looke red, and is first wrought on stickes by the Natives of the Countries (the Ants I meane) then melted being cleered from the stickes, and the winges of the Ants, and made into cakes or thin peeces, which are so brought to us as well as on the stickes, and is the originall of the hard waxe, wherewith Letters are sealed by the helpe of a candle, whose colloures of red, greene, yellow or blacke, are added in the new melting of it againe, and making into such roules as we buy it to spend, but some to adulterate it, and make it cheaper, put usually waxe into it, which maketh it softer and runne quicker: it is called as *Garcias* saith by the Indians in *Pegu*, and *Martaban*, where the best is made, *Trec*, but elsewhere generally by the *Arabians*, *Persians*, and Indians *Loc*, and *Loc Sumutri*, as though it were made in *Sumatra*, but that saith he is not so, for it is but imported thither, and exported againe into other Countries. Great controversies are extant about this *Lacca*, whether it should be the *Cancamum* of *Dioscorides* or no, for the name of *Lacca* was neither knowne to him, nor any of the *Grecians* or Latines, nor yet to *Paulus Ægineta*, a later Greeke writer, or in the age wherein he lived, as *Scaliger* setteth it downe in his notes upon *Garcias*, although *Avicen* and *Serapio* seeme to cite *Paulus* to be of that opinion: but *Garcias* saith that neither *Avicen* nor *Serapio* knew *Lacca*, because they make it to be like Myrrhe, and that it is sweete (as *Dioscorides* saith *Cancamum* is) and therefore used as a perfume, both which properties are wanting in *Lacca*, and further saith *Avicen*, that it hath some properties of *Carabe Amber*, although unlike it in substance, and yet *Carabe* is knowne to be drying and binding, and *Lacca* is an opener of obstructions: And againe he saith that *Lacca* falleth from the aire, upon Service trees, when as neither any Service nor Medler trees grow in India as *Garcias* saith, and that it is the gumme of a tree growing in *Arabia*, and that it is brought from *Armenia*, which things if they be true concerning *Cancamum*, they arē not so for *Lacca*, for so they say it is the *Cancamum* of *Dioscorides*, and from their opinions have the succeeding ages beene led to hold the same errour for the most part: for the Monkes that commented upon *Mesues*, substituted *Sanguis draconis* for *Cancamum*, whom *Matthiolus* confuteth sufficiently: Some againe tooke *Benzoin* to be *Caucamum*, which is as erronious as any: *Amatus Lusitanus*, and *Garcias* doe both agree, that the true *Cancamum* is the Gum *Anime*, called by some *Animum*, especially that sort that is whitish and cleere, like unto white Amber, for there are three sorts brought from *Ginny*, and those parts by the *Portugals*: The second sort is blackish, somewhat like unto *Colophony*, which *Amatus* taketh to be the *Myrrha Aminea* of *Dioscorides*. The third sort is yellowish and dry like Rossin, but all small sweet being burned, and are good against cold griefes. The Lacke or Laake, which is a colour for Painters, is made of Brassill or other dying stuffes, & hath in former times been put very ignorantly by some Apothecaries into the composition called *Dialacca*, but that error is well reformed since the true *Lacca* was brought and made knowne to them. *Lacca* is hot in the second degree, it strengtheneth both the stomacke and liver, and freeth them from obstructions, and dissolveth the hardnesse of the Liver, helpeth the yellow jaundise and driveth forth

*Lacca.* Gum Lacke.

forth the watery humours of the dropsie, provoketh urine and helpeth to breake the stone both in the kidneyes and bladder. Turners may herewith set a firme and dainty red colour into their Workes, by holding it thereto in the turning,

## CHAP. XXXIV.

### *Lapis Bezar.* The Bezar stone.

THe Bezar stone that is now frequent with us, but not that minerall Bezar stone of *Serapio*, and the other *Arabian*, whose knowledge is now quite lost, is of so high esteeme, even next unto Vnicornes horne, and of so much and excellent use in Physicke that I could not leave it out from the number of those especiall drugges we have for use in our shoppes. There are two sorts thereof to be had, the one brought from the East, the other from the West Indies, and knowne by the severall names of their Countries: the East Indie Bezar is the best, both in estimation and use, and commeth to us in sundry formes, and of sundry sizes, for some are great, and those are for Princes and great persons, because they are not onely more rare to be found, but thought to be of the more efficacy, and therefore as Diamonds, Pearles, &c. the price of them riseth according to their greatnesse, *Garcias* saith he had one weighing almost five drammes, as if it were rare to have one of that bignesse, but I have seene some that have weighed above foure ounces, and some much more (but I am in doubt that they were counterfeit, and made so great by art, that they might be of the more esteeme, for I accounto the small ones or those of a meane size to be the truest and best, if any be) some are round, others long or somewhat flat, yet all of them for the most part of one colour, that is of a darke ash-colour, or greene darke Ollive colour, and smooth shining, (as if they were made out of one masse of stuffe and pollished) with sundry coates, scales or fouldes like Onions, some more, some lesse, according to the greatnesse of the stone, and the scales thicker or thinner also thereafter, having in some a straw or peece of haire wrapped close together, or a little pouther in the middle whereabouts the stone is formed, and is accounted the best and truest, others have small stones of fruites, or other things in the middle of them, which are not thought so good, but rather counterfeited, being of a firme substance being broken, I meane the scales: the best is gritty, and easie to be bruised into pouther, and as some say dissolving in water, if it lye long therein (which I am in doubt is a signe of imposture) and is insipide without any taste at all. The West Indie Bezar is likewise of divers formes, sizes, and colours, some having scales thicker or thinner, and some none, with either pouther or peece of a roote, or some other thing in the middle of the stone, but is of nothing that account with us as the East Indian Bezar is, although some thinke they are taken from one kind of beast, and as *Iosua Ferrus* saith in his Booke of secrets, Printed in the *Italian* tongue, (on whose relations concerning these beasts, and the Bezar taken from them, *Baptista Cortesius*, hath commented in his eighth *decade Miscelaneorum medicinalium.*) there are six sorts of these beasts, in the West Indies in whom they breed, but that those onely are of most vertue that are taken from those beasts that live on the hils and mountaines, and feed on the more vertuall herbes there growing, and namely *Contrayerva* as the *Spaniards* call it, which maketh the stone to be the more effectuall (for as *Ferrus* saith, some of the roote hath beene found in the middle of the stone,) they for the most part grow in the Plaines and Champion grounds: the beast as *Monardus* describeth it, being but one of the sixe sorts, is almost as bigge as a stagge, and of the like quicknesse and agility, but bodyed like a Goate, with hornes turned backewards (the figure whereof as *Clusius* was informed, he hath set forth with the forme of an hoofe, as it is in his *Scholia* upon *Garcias*, and I here exhibite their formes unto you with the stones) and therefore the Natives call them mountaine Goates (ye shall have *Ferrus* his full relation of them all, in another worke hereafter) but more properly peradventure as *Clusius* saith, *Rupi capræ* Rocke Goates. (but *Petrus de Osma* in his Letter to *Monardus* describing that beast or Goate, which onely as he saith breedeth in the Mountaines of *Peru*, and in no other Countryes in those Indies beside, and out of which they gathered their

*Lapis Bezar cum ungula & cornuario malis.*
The Bezar stone with the hoofe and horne of the beast.

Bezar

Bezar, ſaid that they had no hornes) and are of a reddiſh browne colour for the moſt part, ſo ſwift of foote that they were onely to be caught when they were killed or ſhot with their Muſquets, the ſtones grow as he ſaith there, in a certaine purſe or skinne in the maw of the beaſt, wherein the wholeſome herbes that they eate are received and kept, untill by rumination and chewing them anew, they paſſe them into their bodies, and ſaith moreover, that the ſtones that breede in the beaſts that feed on the mountaines, are of much more vertue then of thoſe that feed on the plaines: thoſe of the Eaſt Indies as *Garcias* ſaith are had from *Malacca*, and divers other places, as well as *Perſia*, but none are like in goodneſſe unto thoſe that are brought from *Perſia*: The Moores he ſaith are ſo excellent in the knowledge of them, that by ſight they can tell of what Country breeding they be, and whether they be counterfet or no, by cruſhing them in their hand a while, and then breath on them, and if any wind paſſe through them they pronounce them falſe. The ſtone is called as *Garcias* ſaith *Pazar* by the *Arabians* and *Perſians* from *Paſan* which ſignifieth a Goate, but we call it corruptly Bezar, and the Indians *Bazar*, (but *Scaliger* correcteth this errour in him, and ſheweth that the *Arabians* unanimouſly call it *Balzahar*, that is *Alexipharmacum*, for they tooke the word from the *Perſian* word *Bedezahar*, becauſe it reſiſteth poyſon, and we thereupon doe call all thoſe things *Bezardica* that are reſiſters of poyſon, as Antidotes and the like. But the ancient *Arabians* had a minerall Bezar of divers colours, which they celebrated to be of as great or greater efficacy then this ſtone, the true knowledge whereof as I thinke is either utterly loſt, or as *Monardus* ſaith of his owne experience of no worth. This Bezar ſtone is not onely uſed againſt poyſons and venomes, but againſt the peſtilence, and contagious diſeaſes, in malignant feavers alſo, and in many other diſeaſes to provoke ſweate, and thereby to expell evill vapours from the heart and vitall ſpirits, and for ſwounings, and againſt melancholly alſo, and the diſeaſes that riſe from thence, and to preſerve ſtrength and youth, by taking it foure or five dayes together, ten graines or leſſe at a time, after the evacuation of the body: the pouther thereof put on the place that is bitten by any venemous creature, doth free them from danger of death, and likewiſe put into a plague ſore that is opened, it doth the like, *Monardus* hath ſet downe many experiments of the Bezar ſtone, upon ſundry and ſeverall perſons infected with ſundry diſeaſes, as who will may read them at length in that treatiſe which he wrote concerning this Bezar, and the herbe *Scorſonera*: but eſpecially againſt poyſon or venome, and citing the teſtimony of *Rabbi Moſes Ægyptus*, ſaith, theſe three are by experience the moſt effectuall in the world therefore, that is the ſeed of the Citron fruite, the *Smaradge* or Emerald ſtone, and this Bezar ſtone. Theſe teſtimonies I thinke are ſufficient to evince that opinion is held by many that there is no vertue, or at leaſt no ſuch vertue in the Bezar ſtone as it is related, which they thinke by ſome tryall that they have made thereof, and not anſwering their expectation doth confirme them the more in that opinion: but if they have orderly proceeded, and heedfully obſerved, not for one but many times, and in many perſons, and have been ſure of right and good ſtones, that they have given, and yet have done no good, I would rather ſay there is ſome defect in the conſtitution of our bodies, by the moiſture, &c. of our climate, then diſable the verity of ſuch reports of famous and worthy men.

## CHAP. XXXV.

### *Liquid ambar.* Liquid amber.

LIquid Amber is a thicke Roſſinlike Gumme, dropping of it owne accord onely by inciſion from certaine huge great trees in the Weſt Indies that are full of branches, covered with a thicke aſh-coloured barke, having leaves like unto Ivy leaves, which gumme is of a very ſtrong ſweet ſent, ſomewhat like unto *Storax liquida*, and may well be uſed inſtead thereof, but there is another courſer ſort, made by boyling the branches, and ſcumming of the uppermoſt fatneſſe that is gathered there, which is thought to be that *Storax liquida*, that is uſually ſold in the Druggiſts and Apothecaries ſhops: out of the firſt ſort while it is freſh and laid in the Sunne, there droppeth a certaine cleare reddiſh yellow oyle, called the oyle of Liquid Amber, and of ſome that know no other, Liquid Amber it ſelfe: which becauſe it is the purer part is more effectuall and of the milder ſent, ſome uſing it with other ſweetes to perfume gloves withall, but is of ſingular good uſe, either of it ſelfe or mixed with other things, to comfort and warme a cold moiſt braine, uſed like unto an oyntment, and eaſeth all paines and griefes that riſe of a cold cauſe, being applyed thereto: it wonderfully comforteth and ſtrengtheth a weake ſtomacke, helping digeſtion and procuring an appetite, but more effectually if it be mixed with ſome *Storax*, and a little Muske, and Amber, and laid as a plaiſter to the ſtomacke: it likewiſe is profitable in all cold griefes of the mother, warming mollefying and diſſolving all tumours, and opening the obſtructions and the courſes that are ſtopped, it is hot almoſt in the third degree, and moiſt in the firſt.

## CHAP. XXXVI.

### *Macer Græcorum.* The *Græcians* Macer.

MAny taking *Macer* to bē *Macis*, and both one thing, have erred ēgregiouſly for of *Macer*, *Dioſcorides*, *Galen*, and *Pliny*, have written and ſhewed the faculties; but of *Macis*, which is one of the barkes or coverings of the fruite of the Nutmegge tree, they have not made any mention, being a thing utterly unknowne unto them, for if they had knowne it, they muſt needes have heard and knowne of the Nut or Nutmegge, whoſe covering it is; but *Macer* is as they all ſay, a yellowiſh barke, which muſt needes be underſtood of ſome tree, *Galen* ſaith that *Macer* is of a cold and earthly eſſence, and but little hot: but *Macis* is of much heate and no cold. And *Pliny* ſaith plainely that it is the barke of a great roote, and *Avicen* and *Serapio*, both knew the difference, and entreate of them diſtinctly in ſeverall Chapters, calling this *Thaliſofar*. This *Macer* being called *Macre* by the Indians as *Acoſta* ſaith, is a vaſte

and

and large spread tree,(the barke onely of whose rootes they use) greater then any Elme, whose leaves are sixe or seven inches long,and two inches broad, of a pale greene colour on the upperside,and deeper greene on the underside, bearing a small yellow fruite no bigger then a penny, heart fashion, tasting like an Allmond or Peach kernell, covered with a double thin transparent skin like a bladder, close joyned together, and growing out of the middle of a leafe, which is as bigge as the rest on the tree, but that it is a little rounder pointed, and narrower towards the stalke, being of a colour betweene red and yellow, and crumpled with divers veines therein, and like unto the bladders of the Elmetree leaves: every part of this tree giveth milke as the Mulberry tree doth, and hath very great and faire spread rootes like the *Ilex* or Evergreene Oke, covered with a thicke, rugged and hard barke of an ash colour on the outside, and white within, full of milke while it is fresh, but turning yellowish when it is dryed, very astringent and a little sharpe or biting withall,which vanisheth quickely: it loveth to grow in moist sandy grounds, and killeth all the herbes that would grow about it, and is found in *Malabar Cochin, Cranganor,* and many other places and Islands in the East Indies; the *Portugals* call it *Arbore de las Cameras,* and some *Arbore de Sancto Thome,* and *Macruyre.* The barke of the roote is used much in all the Hospitalls, and of great account with the Indians to cure laskes and fluxes of the belly, or blood, and give it either in pouther mixed with some sowre milke,or steeped in whey all night and taken in the morning, and sometimes if it be needfull as *Acosta* saith, they put some *Opium* to it to make the medicine the stronger, and the *Arabians* put both *Opium* and Nutmegs to it and so cure them:the said barke also stayeth vomitings or castings,and strengthneth the weake stomacke.

---

## CHAP. XXXVII.

*Manna granata & liquida.* Manna in hard graines and liquid or thin.

MAnna is of two sundry sorts, the one hard and in peeces,either greater or lesser, the other liquid or thin like the thinner or at least lesse thicke hony, yet some have thought that the Manna *thuris* was that Manna that was used in shops, but *Monardus* in one of his Epistles confuteth that errour, shewing that it is but the small peeces and dust of the *Thus* or *Olibanum,* that became so by the bruising and rubbing of one peece against another in the carriage. Of the dryer or hard sort there is some diversity for that which is gathered in *Arabia* differeth from that in *Persia,* and called *Transchibil,*being in small graines somewhat like unto Coriander seed, and is gathered as *Rauwolfius* saith, from those trees the *Arabians* call *Agull* or *Alhagi.* Another sort is reddish and gathered from herbes and plants. That of *Persia* is called *Xircast,* that is, *Lac arborum,*the milke of trees and is white like that of *Calabria,* whereof some is as small as Hempeseed, others as big as Allmond Comfits, yet *Garcias* saith that the liquid sort is so called by them. Another sort is gathered in *Armenia,*in great lumpes as *Rauwolfius* saith of a brownish colour. Another sort is affirmed by *Aphrodiseus,* cited by *Niger,* that falling as an honie dew on mount *Libanus* in *Syria,* is by the heat of the Sunne congealed into a hard Sugar which the Inhabitants call *Sacchar,* from whence came the Latine word *Saccharum.* All these sorts are recorded by sundry Authours, some contrarying one another as is aforesaid, and might be much more amplyfied, if this place were fit for it, and therefore as I take it I have taken the truer reports: but whereas some have thought that some of these smaller white sorts might be the Manna of the *Israelites* wherewith they were fed, and therefore called bread, and that from heaven, yea Angels food, not that Angels feed thereon, but κατ' ἐξοχὴν, *per excellentium,*the choysest and chiefest,for forty yeares together in the wilderness of *Sinai* and *Arabia,* it sheweth that such have had little conversation with the holy Scriptures, as a learning not fit for them to understand, which is flat against such conceites divers wayes. First that this of theirs had no purging, but a nutritive quality: secondly it was not so Sugar sweete as ours in taste: thirdly it fell not on certaine dayes, that is on their Sabbaths, although it did all the weeke after: fourthly it fell all the yeare long, and not the Summer onely as our Manna doth: fifthly it vanished away as soone as the Sunne grew hot upon it,but ours is condensate thereby: sixthly it would putrefie if it were kept but two dayes except the Sabbath: And lastly as it is in *Joshua,* the 5. Chapter, and 22. verse. That Manna ceased to fall any more, after they had eaten the corne of the Land, which was the morrow after the Passeover, whereby you may see how vaine the conceites,and long altercations of men are,about those things whereof they are ignorant, or not sufficiently instructed: this is but *obiter,* and therefore to proceed. In *Europe* we have Manna, and called *Calabrina,* as being thought not to be found in any Country besides, but both *Matthiolus* and *Bellonius,* and some others also doe testifie there against, upon their owne sight and knowledge, as *Matthiolus* that in *Goritensi,* and *Tridentino agris,* hee gathered it himselfe and *Bellonius* in *Brianson,* and others in other places, but there is a great controversie and contension amongst many learned men: first whether it be onely a dew of heaven condensate by the cold of the night, or whether it be as a gumme issuing from trees, being incised or wounded as other trees are that yeeld gummes: The Monckes that commented on *Mesues,* and so likewise divers others were confident that it issued from wounded trees like gnmme, and was no dew from heaven, for proofe whereof they alledge that the trees being overspread or covered with any cloath or the like, there would not be found in the morning that any dew had falne thereon,and yet the trees yeelded the Manna, which *Matthiolus* thinking to disprove, saith it cannot sound to reason or the course of nature, but rather that the matter happeneth in this sort, that the dewes falling on the dry barkes of those trees were drunke up by them, and was forced forth againe in small peeces like gumme in the heate of the yeare, not being the proper juyce of the trees, but what it had gained as aforesaid, and that this kinde of Manna was more loose and spongy, and lesse operative then the other, and that this happeneth by the secret and hidden property in nature, especially of those trees to containe this dew in them in lumpes, and not to be liquid as on others all about them: A second controversie is whether Manna be gathered onely from the manured or wilde Ash or no, some affirming it strongly, and others denying it as stoutly, as is before said, that *Matthiolus* and *Bellonius* doe declare: A third controversie is, whether it be onely peculiar to *Calabria,* and *Apulia,* or not, which although some affirme for *Calabria,* yet ye heare as before, it is to be found in many other places. The other sort that is liquid or thin, is gathered both in *Asia* and *Europe* alike, but that of the *Levant* is both more plentifull

*Arabica.*

*Alia rubra Persiana.*

*Armeniaca.*

*Syriaca.*

plentifull, and more both usefull and operative, for although in many *European* Countries, and in our Land likewise a kind of honey or sweete dew hath beene found on trees and herbes in the heate of Summer, and in some places so clammy, that the Mowers sithes cold hardly cut the grasse, for the clamminesse thereon, untill the Sunne had beene some time thereon to consume it and dry it up. The *Arabians* and others call it *Terenjabin* and *Trangibin*, the Greekes as *Galen* saith δρόσομελι & εἰρόμελι, and *Cordus* thereafter *Drosomeli*, *Pliny* calleth it *Mel ex aere*, or as others, *Mel aereum*, *Mel roscidam*, or as *Hipocrates*, *Cedrium mel*, and others *Manna liquida*, or as *Matthiolus*, *Manna purgatoria*: but a little to shew you my minde concerning these sorts of Manna, that as the liquid sort is both for substance and property alike, but that the *European* is not so plentifully to be gathered: So I verily thinke that the diversities in the other dryer, both for forme of greater or smaller peeces, or colour of white browne, or reddish, is rather from the climate and dispositions of the Heaven to be hotter or more temperate: but it seemeth to me very strange if true, that in *Calabria* onely the *Fraxinus* or *Ornus* should sweat out Manna, by lancing their barkes, when as in other countries both of *Europe* and *Asia*, it is gathered from sundry other trees, where no sort of Ashes grow, and that no Authour mentioneth any cutting of their barkes, to cause them yeeld Manna. You heare my opinion, whether true or false, I leave to them that can verifie or disprove it, by proofe, and true judgement. The properties of both these sorts of Manna are neere alike in purging, being of a meane temper, yet a little more enclining unto heate, or as *Averrhoes* saith, hot and moist, for by their gentle working they may safely be given to children, and women with child, and put with other purgers they helpe their working and evacuate choller: but because the grained Manna is both more frequent and more of use with us (the other being seldome seene or used) I will rather insist on the properties thereof which is that beside the purging quality, it quencheth thirst and doth lenifie the hoarsenesse of the throate, and allay the sharpenesse of choller, and the nauseous humours in the stomacke: the often use thereof for those that are much given to be costive is very profitable, to be either taken alone or to be put instead of Sugar into broches, drinkes, or other things.

## CHAP. XXXVIII.

### *Moschus.* Muske.

MVske is a precious matter, and both is and hath beene of great worth and esteeme, not onely to perfume things with, but for medicine to great good use: The beast is deciphered out by some to be a kind of wild Goate, or Bucke Goate, that is, betweene a Bucke or Deere and a Goate, and therefore some call it *Dorcas Moschi*, others *Gazella Indica*, and some *Capreolus Moschi*; others make it to be like a Foxe, others like a Greyhound, and some a goodly reddish beast *Gudderi*, some againe say it breedeth onely in *Golchanda*, and some say in *Pegu*, a Country in the East Indies, and most store in the Country of the *Tumbascanes*, others say in *China* or *Cathaya*, others againe say none breede in *China*, but is brought thether from other places: It hath a big body, and two tuskes say some, others say two above and two below, in the lower mandible of the jaw, sticking forth like a Bore or Hogge, and without hornes say some. This beast as it is said by some, when it is in the heate of lust hath a certaine swelling rising thereby at the stomacke, the blood and matter gathering together, raiseth an Impostume or bile, which the beast desirous to be eated of, refusing meate and drinke in the meane time untill it be ripe, doth then rub it selfe against the stones and stumpes of trees, whereby the Impostume breaking the matter congested sticketh on those thinges, which by the heate of the Sunne and temper of the climate is hardned, and all the ill sent (if it have any) consumed thereby, the perfect sweet sent remaining, and this is the best and choyfest Muske is to be had, and gotten by great persons, chiefly to serve their use. Others report that every full Moone it hath neere the navell under the belly an empostume, or bladder full of blood, which the hunters after they have taken them, doe cut of and dry them in the sun, which becometh the best Muskes. But there are other sorts besides those that are more plentifully to be had and sold to the Merchants, gotten and made by art: for having hunted those wilde Goates and killed them, they cut them in peeces, presse out the blood and dry it, and sometimes putting a little of that purer Muske thereto, they put it up into small purses as it were made of the said beasts skin, and this is the usuall Muske sold by these counterfeiters and false deceivers. Besides the great use of Muske, for all sorts of perfumes, and to weare about one, it is very beneficiall to comfort the heart and fainting spirits, and taketh away the passions and trembling thereof, maketh it merry and joyfull, and helpeth to expell sadnesse, it comforteth warmeth and refresheth the braine and senses, quickening the dullnesse thereof, and is a helpe unto Venery: it is put into many cordiall pouthers in our shops, and into many other compositions for the same purposes, as also for delight into many other things. It hath beene observed by some that the dung of a small beast, that is like a Weasell called a Marterne, smelleth somewhat like Muske. The female Crocodile also hath a small bladder or skin about the maw, which smelleth so strongly of Muske, that the waters wherein they breed, and are plentifull of them smelleth so strongly thereof, that few can abide to drinke thereof, and most doe refuse it therefore. There is also a kinde of great water-Rat that smelleth like Muske, &c. But I reserve the relation of the many wonderfull Workes of God in nature, to another Worke.

## CHAP. XXXIX.

### *Mumia.* Mumme.

THat which is called *Mumia*, of *Pomponius Mela*, *Condita corpora & Medicata funera*, of *Pliny*, *Servata corpora* (being of much and excellent use in all Countries of *Europe*) is the very body of a man or woman; (brought chiefly from *Egypt* or *Syria* adjoyning, and no other part of the world so good) Embalmed after the manner was used in those Countries onely, (and not with Aloes, Myrrhe, &c. as being

being those things the *Iewes* and others used to embalme their dead bodies, nor yet with *Pissalpalthum*, as it is likely other nations did) which was with *Cedria* and *Nitar*, that did so consume the moisture of the carkase, and preserve it from putrefaction, that it was thereby made to endure entire and unconsumed for ever: for the *Egiptians* in former times being wonderfull ingenious, and of a most subtle knowledge in all humane wisedome, (as it is recorded of *Moses* to be learned in all the wisdome of the *Egiptians*, *Acts*. 7. 22.) misliking as it should seeme the custome of the Latines, which was to burne their dead bodies to ashes, and to preserve them in an urne: as also that of the *Greekes* to bury them whole in the ground: would to excell them take another way to preserve their bodies, (expecting a resurrection as it is thought) from either fire (which as they were taught by their Phylosophers was a monstrous beast, that devoured all things untill it was full, and then perished or dyed with that which it had devoured) or water, or earth that wormes should not consume them, and therefore with Nitar as with salt they preserved the carkase from corrupting and stench, and with that Tarre, and Tarre water, called *Cedria* (which was made from the stickes of both the Cedars burnt, as is used to make Pitch, and Tarre, from Pine and Pitch tree stickes with us) they besmeared oftentimes the body all over, and wrapping them in many fouldes of linnen, which did so burne as it were, and consume by time all the moisture both of flesh and bones, that it became wholly blacke, as if it had beene burned in the fire, and hard that it was not to be parted in sunder without strokes and beating; but those things that were put into the belly of the dead bodie, could not preserve the whole body, and make every part blacke alike, as I thinke. All the dead bodies of *Egipt*, and *Syria* likewise being thus embalmed were they never so poore, but with more sumptuousnesse and cost peradventure, of Aloes, Myrrhe, Saffron, Balsamum, and other precious things, if they were rich, or the Princes or Kings & were carryed into a desart or barren place in *Egypt*, and laid with some monument or heape of stones on them, which is the place where the Pyramides now stand (as it was the custome in all places to bury the dead in those places which were most barren, and not fit for husbandry, tillage, or pasture) and is about foure miles from *Cairo*, the River *Nilus*, or some branch thereof being betweene, which they must passe over either by bridg or boate, before they come there, and this as it is most likely, was the originall of the *Greekes* fables of *Lethe*, *Stix*, *Charon*, *&c*. The store of *Mumia*, that hath, and is yearely spent in all Countries, doth testifie the innumerable store of bodies buryed there sought for and brought from thence, which are all alike in substance, without any great or manifest difference. There hath beene much controversie hereabouts, the *Arabians* taking *Mumia* to be *Pissalphaltum*, and so did *Matthiolus* also, *Brasavolus* to be *Asphaltum Indaicum*, and to be used instead thereof, which *Matthiolus* misliketh, and seemeth to allow better of the *Pisasphaltum*, or the Aloes, Myrrhe &c. wherewith the bodies were stuffed, being altered in time by the moisture of the carkase in the grave, as is before said then of the body it selfe, which is called *Mumia*, and therefore would have bodies to be so embalmed and kept, that the embalmings might be used, but assuredly, neither the one nor the other can be called *Mumia* rightly, nor are of that effect, for although *Serapio* and *Avicen* say that *Pissasphaltum* and *Mumia* are all one, and therefore whatsoever property *Dioscorides* appointeth unto *Pissasphaltum*, the same they attribute unto *Mumia*, which was their errour, yet *Galen* and *Paulus Ægineta*, by saying that *Pix liquida*, is a fit substitute for *Pissalphaltum* doe intimate that it is of another quality then *Mumia* is, and commeth farre short thereof: It is hot and dry in the second degree, and easeth the paines in the head, comming of cold and moisture, the Megrome swimmings, and falling sicknes taken in a decoction of Marjerome, & helpeth a cough taken in ptisane drinke, it is cordiall for the heart and preventeth the danger of poyson, or the venome of the Scorpion and other serpents, dissolveth winde both in the stomacke, spleene and bowels, stayeth the hickocke and bleedings, both inward and outward, dissolveth the congealed blood of bruises by fals or otherwise, and helpeth the ulcers of the bladder, and the retention of urine, being taken in Goates milke: it is also very profitably used against palsies, crampes, and distentions of the mouth, the hardnes and shrinking of the sinews, and lamenes in the feete through cold and wet.

*Mumia.* Mumme.

## CHAP. XL.

### *Myrrha.* Myrrhe.

MYrrhe is the gum of a certaine tree growing in *Arabia Æthiopia*, and other places, as it is thought *Theophrastus* and *Pliny* declare the various reports of the face or shew it beareth, one contrary to another, so that it may be doubted whether any of them be true, seeing they be but guesses at the likelyest report. I have not heard or read, that any now adayes hath seene the tree that beareth it. *Dioscorides* saith that it is not unlike to the *Egiptian* Thorne, meaning *Acacia*, without mentioning any report, and is gotten

ten by cutting or wounding the tree, that the gumme may flow forth, in the canicular dayes, as other gummes are gotten. We have many sorts thereof, in goodnesse some better or worse then others, as in great and small peeces, fat and dry, pulverilentous like, pale and more red all alike, or else discoloured, with some whitish peeces in it, which is the best, for whereas *Dioscorides* commendeth that which is somewhat greene, I have not seene any such, nor read that any hath ever seene it, and it is very likely that the Greeke word ὑπόχλωρος, which *Dioscorides* useth, may be used *pro colore pallescente*, as well as *subviridi*, and so *Rondeletius* noteth it in his Chapter *de Gobio pisce*, and to be taken here in the former sence. Myrrhe as I said before is in sight so like unto *Bdellium*, that they are sooue mistaken by those that are not expert, but hath these notes and differences: it is extreame bitter, and so is not *Bdellium*, it is paler, fatter, easier to be broken, and of a more quicke sharpe sent, so that the best Myrrhe, may be both knowne of it selfe and hereby from *Bdellium*, that it is of a purplish browne colour, in great peeces and fattish (for the greater peeces retaine their fatnesse longer, and are not so soone dryed by the ayre) with some whitish peeces or veines therein, extreame bitter in taste, and smelleth somewhat sharpe and bitter withall. Divers have diversly thought of Myrrhe, some supposing Myrrhe to be *Benzoin*, and *Bdellium* to be Myrrhe, and that we had no true Myrrhe, *& e contra*, that we had Mirrhe and no true *Bdellium*, because so little that was good, was formerly brought to be used, that they might be plainely distinguished, and the rather because that *Galen* saith Myrrhe, will be sometimes changed into *Opocalpasum*, which is venemous and deadly, and is so like it, that as he saith in his time many were killed therewith, who yet finding it to be very effectuall for sundry diseases of the eyes, thought it might be as effectuall for inward diseases: the notes of which *Opocalpasum* (as *Galen* calleth it, or *Opocarpasum* the juyce of *Carpasum* as *Dioscorides* calleth it in his sixth Book and 13. Chapter among the venemous plants, but maketh no description thereof in any of his former Bookes) as I finde them set down in *Weckers Antidotarie* in the examination of Myrrhe) are these: because saith *Wecker* true *Opocalpasum* is not usually to be seene to compare it with Myrrhe, yet if you shall perceive in Myrrhe some peeces to be much differing both in sent and taste from true Myrrhe, you may wel & not without good reason judge that it is changed into *Opocalpasum*, for although both in colour and substance it be like to the best Myrrhe, with whitish veines therein like unto the nailes of ones hand, yet examining it more thoroughly, it will be found not to be Myrrhe, and that there will likewise some reddish cleere spots appeare therein: it behoveth therefore to be cautelous in the choyse of Myrrhe, that you be not deceived with the shew or likenesse, but observe that it have all the true notes of true Myrrhe, least while you thinke you have the true Myrrhe, you have this poyson, if it be inwardly taken, which consumeth the corrupt mattering and watering of the eyes to be used outwardly: which metamorphosis (if it be true, or that *Galbanum* should be changed into *Sagapenum* or *Cassia* into Cinamon were very miraculous yet herein the old Authours are very frequent, but I thinke of these miracles, which are the conversions of substances, as I doe of their transmigration of soules) *Dioscorides* maketh no mention of it, but saith that the juyce of *Carpasum* (whether herbe or tree) was venemous as *Taxus*, *Cicuta*, and many other was, and to be cured with the same remedies that *Cicuta* was. *Dioscorides* saith that out of the fattest Myrrhe called *Pediasimos*, being pressed is taken *Stacte*; yet *Pliny* saith that the trees doe sweate out *Stacte*, of their owne accord before they be cut, which is accounted to be the *Styrax liquida* of our shoppes, both by the *Arabians* and other later writers as *Matthiolus* saith, himselfe also being of that opinion, whereof I cannot but mervaile that he or any other duely considering our *Styrax liquida*, both the forme and sent so farre differing from Mirrhe, should thinke it to be pressed out of fat Myrrhe, being of so fine a sharpe bitter aromaticall sent, and the *Styrax liquida*, rather loathsome then pleasant. *Dioscorides* maketh mention of one sort of Myrrhe called *Aminnea*, which *Galen* calleth *Minea* (*Matthiolus* taking them to be divers, and not one sort of Myrrhe) which some thinke to be the Gumme *Anime*, called by the *Portugalls Gum Anijmum*, comming from *Ethiopia*, for there is another of the West Indies whereof I shall intreate hereafter, but herein I thinke they are deceived. *Galen* saith that Myrrhe is hot and dry in the second degree, and therefore is good for wounds in the head: and by the bitternesse which is not little, it killeth the wormes in the belly, and the living childe, expelling the dead: it hath in it also a binding quality, whereby being mingled with eye medicines it helpeth ulcers and great scarres, and for the same cause is good to be put among those things are good for an old cough and shortnesse of breath, the bitternesse not harming the winde pipe or throate, but gently clensing and heating, it helpeth the roughnesse of the winde pipe or throate, saith *Dioscorides*, and those that are hoarse, and have lost their tongue as we call it: it is good also against the paines of the sides, the laske and bloody flix, and rheumaticke destillations; it speedily procureth womens courses and mollifyeth the hardnesse of the matrix; it also taketh away the shivering fits of agues, being taken two houres before it come: but *Matthiolus* saith that by taking a dramme of Myrrhe in Muscadine, using it three times, an houre before his fits, he was cured of a quartaine ague, but he did therewithall presently after the taking thereof sweat moderately in his bed: pilles likewise saith he made with it and Treakle, is effectuall for the same purpose, to take one at a time as bigge as a pease, an houre before the fits for many dayes together: it is also a great preservative in the Plague or pestilence, and against the venome or poyson of Serpents and harmefull creatures, and therefore is put into Antidotes and counter poysons: it is a singular remedy for a stinking breath, fasteneth loose teeth, and

*Myrrhe truncus cum Gummi.*

stayeth

ſtayeth the ſhedding of the haire, being uſed with *Ladanum*, and the wine of Mirtles, it helpeth mattering eares and watering eyes, and taketh away the filme or skinne that beginneth to grow over and darken the ſight, it helpeth to breede fleſh in deepe wounds, and to cover naked bones, *Matthiolus* commendeth it as a ſingular *fucus* for the face to take away wrinckles that come by age, and to make it ſmooth and youthfull to be made into an oyle as it is called, or rather the liquour of Myrrhe, which is made with egges boyled hard, cut in the middle, the yolkes taken forth and filled up with pouther of Myrrhe, then put into a glaſſe and ſet in a Wine celler or moiſt place, and with this liquour to be bedewed: As alſo another way, that is, by ſprinckling with white wine, a new iron diſh or pan made hot in the fire, and taking firſt the fumes thereof unto the face, being covered over with a cloth. and then the fumes of Myrrhe in pouther, afterwards caſt on it being heated againe, and the head covered as before, and this ſtill to be uſed before bed time, for eight dayes together.

## CHAP. XLI.

### *Nardus Indica ſive Spica Nardi.* Spicknard.

*Garcias ab Orta*, intreating of this Spikenard teſtifieth that there is but one ſort knowne, and uſed as well by the Indian and *Turkiſh*, as the *Perſian* and *Arabian* Phyſitions, and although ſome would intimate that this is not that was uſed by the Ancients, in that *Pliny* ſetteth it downe *lib* 12. *c.* 12. that it was not to be had but at an exceſſive price, yet that hindereth not, in regard both all the Countryes of the Indies are better husbanded then heretofore, and eſpecially that ſince the *Portingalls* had opened the way by Sea, all ſorts of Drugges were provided better and better cheape by much, the charge of *Caravans* being exceſſive chargeable by their long journey and travaile, but I thinke both the Drugges and the Indies, by being more ſought by *Venetians* and other Chriſtians was the beginning of the reformations, for when *Arabians* and the like were the chiefe Merchants, much bad Merchandize was dearely ſold, howſoever cheapely bought, and I thinke much more adulterated both by them and Iewes, and the Indians alſo were not behind to ſophiſticate whatſoever they could, which the Chriſtians I verily ſuppoſe did ſomewhat alter, when they became great Merchants for *Europe*, and ſince is rectified more and more, when onely the ſincere and pure is bought, and the other left on their hand to mend if they can, but yet it falleth out that the blinde eateth many a flye, I meane the ignorant is often deluded, who through covetouſneſſe oftentimes letteth paſſe the better to take the worſer at cheaper rates: but to the purpoſe in hand. This Spicknard groweth not in many places, and where it doth, it is not very plentifull; it is a roote yet called a Spike, becauſe it ſhooteth up hairy ſtalkes of hairy like Spikes, many ſet together, of a brownifh colour, and whereas *Dioſcorides* ſaith the roote is of no uſe, yee muſt underſtand the word in a double ſenſe: the rootes that *Dioſcorides* meant, be the ſhort fibres, whereby it draweth its nouriſhment and encreaſe from the earth, and theſe indeed be unprofitable and of no uſe; but the rootes that *Galen* ſpeaketh of, are the Spikes themſelves or Spicknard, for ſo he calleth them both, *lib.* 1. *De Antidotis*, thus ſaying; *Iubet Andromachus adijcere Nardum Indicam, ea vero eſt quam ſpicam vocant non quod ſpica ſit radix enim eſt, ſed quod ſpicæ formam referat.* And in *lib* 9. *de comp. med. ſec. locos.* He uſeth ſomewhat neere the ſame words: but in that ſome object, it is not of a ſweet ſent, ſuch as *Dioſcorides* recordeth of it, *Garcias* ſaith while it is freſh it is ſweete, but time may decay ſome part of the ſent, and beſides ſweete ſmells were otherwiſe taken with the Auncients then with us, witneſſe many things, as *Galbanum Allium, &c.* were reckoned ſweete, much differing from the opinions now received, but thus I have ſhewed you the acception of the roote and Spike of this *Nardus* and the ſweetneſſe: Both *Dioſcorides* and *Pena*, have recorded that it doth beare a ſtalke and leaves, yet have not mentioned what flowers it hath, neither is the other baſtard or *French* Spikenard of *Lobel* ſhewed to have any, which I have exhibited in the firſt Claſſis of this Worke, but the like was found in *Virginia* by Maſter *Iohn Tradeſcant* the younger, with ſuch like long greene leaves as is deſciphered in that, the roote alſo anſwering ſo neere unto the *French Nardus*, but of a paler blackiſh colour, and without any ſent that I could perceive, and beſides all this, he found it with the ſpike of flowers and ſeed at the toppes of the ſtalkes, which were turning or winding, the head ſtanding on a ſmall naked ſtalke, ſomewhat like (I meane in the turning) unto the *Scorodo praſſum anguinum*, or *Convoluto capite*, the great Turky Garlicke with a twined head, conſiſting of two or three rowes of ſmall bright brownifh chaffie huskes, hairy as it were at their ends, and ſtanding all on one ſide of the ſtalkes, for foure or five inches long. This baſtard kinde bearing ſuch an head, doth perſwade me to thinke

*Nardus Indica.* Spicknard.

this Indian kinde to have also some other, whether the like or no is not to be determined but by sight, The properties of this Indian Spikenard are these: It is of an heating and drying quality, provoking urine, and staying laskes, and both the reds and whites in Women: it taketh away the loathing to meate, and the gnawing of the stomacke usually called the heart-burning, it conduceth helpe to swellings, to the stone in the kidneyes, and to the Kings Evill: the decoction helpeth the inflammations of the mother if they sit therein: it helpeth to bring haire on the baire eye lids: it is not onely an ingredient into the two famous Antidotes, *Theriaca Andromachi*, and *Mithridatium*, but into sundry other compositions appointed by the Ancients, but because I would not make a double repetition of the same things, having declared the properties hereof at large in the 42. Chapter of the first Classis of this worke, I must referre you thereunto.

## CHAP. XLII.

### 1. *Palma sive Nux Indica vulgaris ferens Coccos*, The ordinary Indian Cokar Nut.

THere cannot be found in the world, a tree that hath so many necessary commodities for mens uses to be had from it, as this Cokar Nut: the tree groweth to be huge great and vaste, whose body or stem is covered with a smooth barke, bare or naked without any branch to a great height (for which cause the Indians doe either bore holes therein at certaine distances, and knocke strong pegs into them which sticke out so much as may serve for footing to get up into the tree, to gather the juyce or liquour and the fruite, or fasten ropes with nayles round about the tree at spaces which serve as steppes to goe up into it) and toward the top spread sundry great armes which bowe themselves almost round, with large leaves on them like the Date tree but greater, whose middle ribbe is very great, abiding alwayes greene, and with fruite also; continually one succeeding another: from betweene the lower boughes come forth smaller stalkes hanging downe, bearing sundry flowers on them like unto those of the Chesnut tree: after which succeed large great three square fruite or nuts, ten or twelve, or sometimes twenty thereon together, as big as ones head, or as a small Pompion almost round, but a little smaller at the end, covered with a hard tough darke ash-coloured barke, and within it an hard round wooddy brownish shell, but blacke being polished, having at the head or toppe thereof three holes, somewhat resembling the nose and eyes of a Monckey, betweene which outer barke and this shell, grow a number of grosse threds or haires, or such like stuffe, whereof is made cordage, stronger and more durable in the salt Sea, then any made of hempe; within the wooddy shell, there is a white kernell, cleaving close to the inside thereof, of the thickenesse of ones finger or thumbe, or thinner, as sweete and pleasant as an Almond while it is fresh, having in the middle thereof a pint, two or three, of cleare dainty sweet water, as pleasant as milke,

*Palma vel Nux Indica Cocos ferens.*
The Indian Cokar Nut tree.

*Nucula Indica racemosa.*
A small Indian Nut many growing together.

but

*Fructus integer Nucis Indicæ Cocus dictus.*
The whole Cokar Nut as it is taken from the tree

*Nux Indica interior.*
The inward Cokar Nut with the hard blacke shell thereon.

*Nucula Indica alter.*
A little Indian Nut, and another called *Mehenbethene*;

but as it groweth either to be over ripe, or being kept to be older, so much lesse pleasant will this liquour be, and either grow sower or thicke by time, and be quite spent and consumed, it hath beene observed that sometimes there will be floting in this liquour a small lumpe or ball, as cleere as a pearle, and very sweet in taste, which is as the sprout, which have sprung forth a stalke rising through one of the holes at the head, and rising two palmes above it hath shot forth fibres for rootes. The name and uses whereunto this tree, and the fruite, and those things that are made thereof serve, are these. The tree it selfe is called generally by the Indians *Maro*, in *Malaca Trican*: but in *Malabar Tengamaran*, by *Avicen Giausi al hend*, which is *Nux Indica*, by *Serapio* and *Rhasis*, as *Garcias* saith, *Iarelnare*, yet that word is not found saith *Clusius* in our Bookes, but *Neregill*: the Latines call it *Palma Indica & Coccifera*, to distinguish it from the *Palma Dactylifera*, the timber whereof is not spongy or like the *Ferulas* as *Garcias* saith, but solide and firme, blacke and shining like the Wallnut tree, fit for building of houses or ships, and other things, as *Garcias* himselfe saith a little after, this tree saith *Garcias* is of two sorts (or rather as I thinke kept for two uses) the one to beare fruite, the other to extract the liquour issuing thereout, when the branches are cut, or when it is bored and received into Gourdes, or other such like things tyed thereto, which liquour they call *Sura*, and is like troubled Wine in shew, but in taste like new or sweete wine which being boyled is called *Orraqua*, and being destilled is made like unto *Aqua vitæ*, which they use to the same purpose that we doe ours, and will burnē likē it, and is called *Fula*, and being set into the Sunne will become good vinegar, but that which runneth last being suffered to abide in the Sunne untill it grow hard, or boyled to the hardnesse will be Sugar, which they call *Iagra*. The branches saith *Garcias* (but *Ferdinandus Lopes* saith the leaves) are called *Olla*, and serve as umbrels to keepe off Sunne and Raine, and in such like leaves, saith he, was written the first Letter that the King of *Calecut* sent to *Emanuel* King of *Portugall*, upon the *Portugals* first arrivall into his Country, they serve likewise to cover houses, to be defended from raine, the fruite is called by the Indians generally *Narel*, which is common both with the *Persians* and *Arabians*, but in *Malabar Tenga*, and while it is greene and not ripe *Eleni*, the *Portugals* call it *Coquo*, that is a Monckey, of the likenes of a Monkeys face, and from thence hath risen the word *Cocus* or rather *Coqus*, which the three holes represent, and at *Goa Lanha*, of the hairy stuffe or hardes which is next the outer barke of this Nut, called by the Indians *Cairo*, are made not only Cordage and Tackle for ships, but cawking stuffe, which is better to cawke ships then any other stuffe, and being beaten, the finer stuffe is made into girdles and cawles for women, (sailes cloathes also, but not any fine stuffe or cloath like any fine linnen) both of the meaner and better sort at *Lisbbone*, as *Clusius* saith he saw and observed, but as *Garcias* saith, while this Nut is young it hath a tender barke which may be eaten, and tasteth like an Artichoke; of the browne hard inner shell, being pollished and made blacke and shining, is not onely made cups, to drinke in, set in silver or other mettall, which made *Sepulveda* to draw the *Portugalls* to thinke that it doth helpe those that have the Palsie to drinke out of them, but *Garcias* saith it hath no likelihood: but being burned into coales serve the Gold smithes for their uses: who goe about in the streetes crying for worke, and carrying some necessary tooles for the purpose with them; of the inner white kernell, which is hollow, cleaving fast to the inside of the hard wooddy shell, which is an inch or two or lesse thicke, firme and fast, tasting sweet like an Allmond, they make bread especially while it is fresh, for the fresher the Nuts are, the sweeter will the meate thereof be, and doth nourish much, being good for macilent bodies, and to encrease sperme and Venery, and is good to lenefie the harshnesse of the throate, and the hoarsenesse of

the voyce, and eaten oftentimes with *Iagra* before recited, or with Sugar, or else being broken and bruised they draw forth a milke, like unto Allmond milke, wherewith they boyle Rice, and is as sweet as the milke of Kine, or Goates, or else herewith, and the flesh of beasts or birds, they make certaine meates, which they call *Carib.* The fresh kernels being broken and dryed after the outer rinde is pared away, are called by them *Copra*, and is sent as a merchandise into other Countryes, that have either none or not sufficient store to serve their use: which taste much pleasanter then any of those that are brought from thence into these parts, it is used also as a stirrer up of Venery, and to encrease sperme or seed: Out of this *Copra* or broken kernells is made two sorts of oyle, the one pressed forth (after the same manner that oyle of Allmonds is made) and is a most cleare oyle in good abundance, which serveth not onely to burne in Lampes, but to put to their boyled Rice: the other is made by putting warme water to them after they are broken to peeces and boyled, by scumming off the oyle that swimmeth above the water, after they are pressed together, which oyle is used as a gentle purgation to evacuate the bowels, some put thereunto the pulpe of *Tamarindes*, which maketh it a little tarter, and fitter for hot and cholleric bodies, the other oyle serveth to mollefie the hardnesse and shrinking of the sinewes, and old paines in the joynts, and for this purpose they use to put the patient after he is annointed, into a great and capatious tub or vessell being heated, that may hold him, and therein suffer him to abide for a good while, untill he have slept therein, and this bringeth him a great deale of ease and comfort: but whereas *Avicen* saith, that it killeth wormes, *Garcias* saith he had not tryed it, neither thought it probable, because it is well knowne, that the eating thereof ingendreth wormes, in all the Inhabitants that eate much thereof, and is a disease incident unto them: and whereas *Serapio* saith, by the authority of *Mesues*, that by the eating of these Nuts, the loosenesse of the belly is stayed; it disagreeth not with reason, saith he, that the Nut it selfe, which hath much earthy parts in it, should binde the body, and the oyle which is of many thinne and aerious parts should loosen it: in the middle or hollow part of this kernell is contained, as is before said, a great quantity of cleere sweet liquour, pleasant to drinke, and not bringing any offence to the stomacke, but rather refresheth the spirits, the other sort of these trees are reserved saith *Garcias*, that the head sprout or top thereof is taken to be eaten, which tasteth more pleasantly then either tender Chesnuts, or the head of the wild or dwarfe Date tree, called *Palmito*, and by the *Italians Cefaglioni*: The older the tree is, the pleasanter is this head, but when it is taken away, the tree dyeth, so that he may well be said to devoure the whole tree, that hath eaten one of these heads.

*Nucula Indica racemosa.* A small Indian Coker Nut many growing together.

This small Indian Nut which *Clusius* described singly, in the second Booke of his Exotickes, the six and twentyeth Chapter, and 54. page, and the second Nut was afterward sent unto him from Mounsieur *de Peiresc*, in *Province*, but came a while after his death. The tree that beareth these fruites is in great account with the Natives where it groweth, for with the leaves they make their drinke, being boyled with water, and of the kernels of the fruites they make their bread, that is sweet and pleasant, which fruite groweth in a tuft or spike, many together, and all upon a great thicke stalke, they are inclosed in a certaine hairy huske or skinne, breaking open upon the ripening, and each one also hath a hairy huske or covering, under which was another shell or covering, not much unlike to a Filberd, being an inch long, and an inch or better in compasse, being firme and solid, not having any loose or broken kernell within it, whereby to make any noise, but a firme white kernell fit to be eaten, which inner shell had an oylinesse about it, like unto oyle of Allmonds.

*Nucula Indica altera.* Another small Indian Cokar Nut.

The tree that beareth this Nut groweth in great plenty about the *Castell de minas* in *Ginney*, called *Palmes* by the inhabitants, being tall and as great as a good ships mast, bearing leaves at the toppe, of a dozen or fifteene foote long, hanging downewards, cut in like unto Reed leaves, from under which leaves grow branches, the fruite being then as bigge as a mans head, containing within them many divers small nuts greater then Plummes of a gold yellow colour, from whose kernels being bruised, they draw a cleere oyle, which they call the oyle of Palme, which they put into their viands, both for the colour and sents sake: this oyle brought into these parts groweth thicke like butter, and is very yellow, which some that brought it used for the cure of their fresh wounds, and annoynted their arteries and sinewes pained with crampes, and convulsions, whereby they finde much helpe and ease. *Clusius* describeth these Nuts to be three square, and to have three holes as it were, at the heads of them like unto the Cokar Nut, covered with a hairy huske, but the shell saith *Lobel*, is harder then a bone and blacke, whether these be all one I am in some doubt. Further it is said that the Inhabitants by boring the tree, there commeth forth a sweet liquour, almost like the whey of milke, unto which they put a little wild honey, and thereof make their drinke, which they call the wine of the Palme, which will inebriate being largely taken.

*Mehenbethene.* The Indian Nut *Mehenbethene.*

This Indian Nut which *Clusius* saith *Cortusus* sent unto him for *Mehenbethene*, but did little agree, saith he, unto the description thereof, *Lobel* saith it was found among Nutmegs at *Antwarpe*: It is saith *Lobel* both in colour, forme, and greatnesse like unto a Nutmegge (which therefore *Clusius* saith it might be better referred to the kinds of Nutmegs, yet very untowardly I thinke) being about an inch long, and three square, whose shell was hard and wooddy like a Cokar Nut, and being broken had three cels or divisions within it, in each whereof was a small long white kernell, of a sweete and pleasant taste.

2. *Coccus de Maldiva.* The Cokar Nut of *Maldiva.*

This kinde of Nut is accounted as another *Coccus*, it is in many things so like the other, for although it was never seene growing on any tree, as the Indians doe report, the Nuts being onely found upon those Islands of the *Maldiva's*, as the Sea casteth them on the shores, and in no other part of the world besides, and are not lawfull to be reserved by any, on the paine of their heads, but are all brought to the King or his Officers, in that all wrackes &c pertaine to him, and are onely sent by him as presents of great account to other Indian Princes and great persons, &c. Vnlesse by stealth and concealement, some are diverted otherwayes, nor was never seene to have any such rough huske as the Cokar Nut hath, yet in the inner hard shell inclosing the inner kernell it is almost in all points like the other: the whole Nut carrying this proportion: it is farre greater, longer, and rounder then the other (yet there are of smaller sizes also) and of an ovall forme, containing two parts which are so conjoyned

together

*Coccus de Maldiva.* The Cockat Nut of *Maldiva.*

together in the middle almost all the length, that it is but a little separate both above and below, the upper part being somewhat bigger then the lower, that it seemeth as if two long nuts were set together, but cannot be separated by strength of hands onely, but must be sawed in sunder, the shell being so hard that it scarse yeeldeth thereunto without great labour, it is also on the outside much blacker then the other and being polished with the stone *Tripelo* (*Tripoly* we call it) in pouther with water, rubbed with a woollen cloath, (but not with oyle on no hand, for that will give it an evill savour) it will become both blacker and more sweete and shining then the other, as also much thicker, it hath also two holes at the toppes, no lesse then the other *Coçus*, and may be cut into two long boatelike cups, to be edged and footed with silver, &c. as every one please, or else each of them again cut into two other, to be bordered with mettall, the lower brims to be raised therewith, and the holes stopped, as it pleaseth every one to doe, or to keepe them for boxes. *Clusius* setteth forth in the 193 page of his Booke of Exotickes, the figure of the one halfe of these Nuts curiously set in silver, which as he saith, he received from *Jaques Garret* of *London*, being taken by us in a great Carracke of the *Portugals*, comming from the East Indies, which was foureteene inches long, and seven broad. The inner kernell hereof is also somewhat white on the inside, but covered with brownish skinnes both outside and inside, which hath some rifts or clefts, the outside having none, but is much harder then the other, even allmost as hard as a bone, and is a little separated from the woodden shell, which may soone be perceived when it is opened, but may also before, being as it were loose, as may be knowne by the shaking: it is hollow also as the other, as if it contained liquour likewise, but was never seene with any being as it should seeme, wholly consumed by the long time before they were gotten: it hath likewise a small lumpe, as white and cleare as a pearle, sticking to the head of the inner kernell, as the other, which no doubt is the bud which would spring: the kernels on both sides are conjoyned in the middle also. It is usually called by all the Christians and some others in those parts. *Coccus de Maldiva*, by *Augerius Clutius* in his Tractate thereon, *Nux Medica Maldivensis*, but by the Islanders *Tavarcare*. The properties both of the kernell and outer shell, is as *Garcias* saith, generally held to be good against poysons of all sorts and pestilentiall diseases, to be taken the weight of ten graines in fine pouther (which is best to be made in a morter, by beating it, for it very hardly yeeldeth to a File, or any other iron raspe or tooble, the kernell being allmost as hard as the outer shell) more or lesse according as the case requireth: divers great personages have a peece tyed to a chaine, which they put into their drinke letting it abide therein a little while before they drinke, which they account to be as effectuall. It is also saith he, held by divers worthy persons to be availeable against the chollicke palsie, and falling sicknesse, and other the diseases of the head, nerves, and sinewes, and by the use thereof, either of the drinking out of the cups thereof, or the drinke, wherein a peece of the kernell hath beene steeped as is aforesaid, to keepe them safe and sound from all other diseases: yet *Garcias* scarse beleeveth any of these things, and *Clusius* as being led by his ill sample accounteth such relations to be fabulous and commentitious: but *Augerius Clutius* before spoken of, in his tractate of this Nut is bold to publish the sundry cures he performed hereby, that is, both the Nut and the shell, not onely for the poyson of Arsenicke, but in Feavers, Epilepsies, Cachexia's, and many other diseases there mentioned, but especially in the sore and tedious travailes of child-birth, giving halfe a dramme of each, or two scruples for *adose*, either alone or with other *co-adjutors*.

Some thing yet remaines, wherein I would deliver mine opinion concerning some particulars, belonging to this History of the Nut of *Maldiva*. First concerning that opinion is held, that all those Islands have beene formerly joyned to the Continent, which is said to be 150. Leagues distant from them, and broken away by tempests, and innundations, which may be as likely as that our Isle of great *Brittaine*, was also joyned to the Firme land of *France*, and both I thinke alike true, for *Cæsar* found them thus in his Progresse hither, and the Sea hath not in this part gained from the Land, as can be shewed by any good Record. Then that these Nuts because found onely upon the shores cast up by the Sea, that the trees either grow on some of the drowned Islands, their rootes abiding still firme in the ground, yeelding the fruite yearely, and so swimming to Land is taken, where the winde and waves drive them, or that they grow in the bottome of the Sea, as Amber doth, which may be both also alike true, that is neither. Againe, that there is a certaine Island called by them *Palloyes*, whereon some others thinke that the tree that beareth these Nuts should grow, and falling when they are ripe, are carryed by

by the winde and waves to those Islands are next thereunto, (which I thinke in some part may be probable) but that they adde, that this Island is seene by some that looke not for it, but cannot be found by them that seeke it, although as they say, the King hath caused sundry times search to be made for it, still they that have beene sent have returned afrighted and terryfied by spirits, that they have given it over and returned with such answers, which in my opinion are meere fables and noysed of purpose to keepe the Nut in more estimation. But in my judgement if the truth might be searched exactly, by stout and not timerous persons, by religious not superstitious, as most of the Indians are, and by judicious and industrious men, and not weakelings, and fooles, the tree that beareth these fruites would be found to grow on the Land, whether Continent or Island is no matter, and that if it be true that these Nuts are onely found on the shores, as the Sea casteth them up, for even of that report I am more then halfe doubtfull) when they are ripe and falne, the Windes carry them from off the Land whereon they are falne, into the Sea, and so are taken up on those Islands: but yet me thinkes it is somewhat hardly to be beleeved, that these Nuts should be carryed by the Sea to the coastes of no other Countries, but these Islands although they be so many, for the report is that they are not found in any part of the world besides. And lastly, to finish this tedious discourse to shew my opinion how these (if they be fables) may be blowne away, and the truth certainely knowne, *viz.* if either these Islanders, that is, the King, or some of the Naturalls, or else some Christians, or others in those parts would make choyse of the freshest they could finde of these Nuts, and to put both divers of them, and at sundry times into the ground, to see whether they would not sprout forth, and spring, for it is probable, that as they are in the inner kernell, like to the ordinary Cokar Nut, which hath a bud therein that hath and will grow, as is shewed before, This Nut also so neerely resembling it, as is shewed, might at one time or another spring and grow, and take away all other doubts and fables, whatsoever are forepassed: This my opinion how it will be accepted I know not, but if any by the tryall thereof should raise a tree or more, it would prove a worke no lesse gainefull then memorable to all posterity.

## CHAP. XLIII.

### *Nux Moschata.* The Nutmeggē tree,

THe Nutmegge tree, and so likewise the fruite arē of two sorts exactly observed by *Clusius*, and by him called *mas* and *fœmina*, the *mas* beareth the greater and the longer Nutmegge, the lesser and rounder the female, and the most ordinary with us, the tree whereof is reported by them that have seene them, to be very great, and as tall allmost as our Peare trees, spreading many branches, which are greene while they are young, having faire broad leaves set thereon, some what longer then Bay leaves, or to compare them more truely, like unto the Orrenge tree leaves, but without the lower peeces, and

*Nucis Moschatæ termes genuina.*
A true branch of the Nutmegge tree, with the fruite.

*Nux Moschata seu fructus integer concisus cum tegumento Macis, cortice nigro & nuce interiore rotundo & longo.*
The whole Nutmegge cut in the middle, the hard shell with the Macis both on it, and of it, and the Nutmegs both long & round.

not

not so hard nor dented about the edges, but set on a short stalke nót one against another, but unequally on the branches, and abide alwayes greene thereon, the fruite (for flowers have not beene observed) groweth at the end of the young branches, and not as *Matthiolus* setteth them forth, among the leaves, which are as bigge as Peaches, standing singly for the most part, but sometimes two together on a long thicke footestalke, having an outer thicke huske furrowed in the middle, which divideth it selfe into two parts, and growing ripe openeth it selfe, shewing the Nut within, covered with the Macis, cut into severall peeces as it were, and so strictly cleaving to that blacke hard shell whereon it lyeth, that it leaveth the print of the lying of it thereon, and is of an orient crimson colour, while it is fresh and the huske newly separated for it to lye open, but by little the ayre changeth the colour to be more dead and yellowish, as we see it brought dry unto us, being taken of from that blacke, thinne, hard shell, that encloseth the Nutmegge it selfe within it, which is somewhat round and firme or solid, diversly discoloured in veines within, somewhat heavy also, I meane the best, and not light or hollow, and yeelding an oylie moisture upon the pricking thereof with a pinne or needle, and of an excellent aromaticall both sent and taste, yet not so quicke and hot as either Pepper, Ginger, or Cloves.

The other whose Nutmegge is longer and accounted the male, a branch whereof *Clusius* exhibiteth a part from the other, and describeth it as he received the branch, which was of a foote and an halfe in length, and as thicke as a writing pen of a goose quill, retaining some of the old wood of the last yeare, whose barke was of an ash-colour, but the new sprung branch of a brownish red colour, and very pithy in the middle, this branch had seven or eight leaves on it, being much larger and with a thicker footestalke then the former, and were neere a foote long, but not much thicker then they, and three or foure inches broad, somewhat hoary underneath and greene and shining above, with divers veines thwarting the middle ribbe: the fruite groweth in the same manner as the former, at the ends of the branches, but more in number set together, in all things like the former, but longer and greater, and nothing so aromaticall in sent and taste, yet it is said that the Macis of this sort is much more orient in colour then the last. They have received sundry names, for in *Banda* where they grow best they call them *Palla*, and the Macis *Bunapalla*, but in *Decan*, *Iapatri*, and the Macis *Jaifol*: of *Avicenna Iausi band*, that is, *Nux Bandonsis*, and the Macis *Befbase*. This was not knowne to the ancient Greeke writers, *Theophrastus* or *Dioscorides*; no nor to *Galen* or *Pliny*, for although some have thought it might be *Galen* his *Chrysobalanos*, yet they are farre awry therein, the later have called it *Nux Aromatites*, *Nux Myristica*, and *Moschata*, as if it were derived a *Musco*; for the sweetnesse thereof. They are used in all the cold griefes of the head or braine, for palsies, the shrinking of sinewes, and the diseases of the mother, they are hot and dry in the second degree, and are somewhat astringent, serving to stay the laske, they cause a sweet breath and amend a stincking, they helpe to discusse winde, either in the stomacke or bowels, it helpeth to quicken the sight, and to comfort the spirits, and provoke urine, and are comfortable to the stomacke, and helpe those that are feeble or macilent to grow fat as also helpeth Venery and encreaseth sperme, they helpe to procure rest and sleepe by allaying the distemper of the spirits, being applyed to the temples. The Macis are of the same property, but somewhat more warming and comforting, the thicke oyle that is drawne both from Macis and Nutmegges, are either of them of good use in pectorall griefes to warme a cold stomacke, and the cough, and to dry up rheumaticke destillations of raw and cold flegme thereunto or upon the lungs. The chimicall oyle of either is of more efficacy both for pectorall and cephaticall diseases, but must be cautelously and sparingly used.

---

## CHAP. XLIV.

### *Nux Vomica.* The Vomiting Nut or *Nux vomica.*

ALthough we have no true knowledge of the tree that beareth these Nuts (as they are called now adayes ordinarily in our shops) more then what *Serapio* saith of it, that the tree of the *Nux methel*, is like the tree of the *Nux vomica*, whereby we thinke that our *Methel*, which is the *Stramonium minus* with us so called, is the *Methel* of *Serapio*, but are much deceived, for his differeth much from it that we so call, in that *Serapio* saith of his *Methel*, that it beareth an oily fruite like *Mandragoras*, with an hairy skin or barke, and of no unpleasant taste, and of his *Nux Vomica* he saith also (differing notably from ours) that as one *Abraham* had informed him, it was a fruite bigger then an Hasell Nut, full of nodes or bunches, and of a colour betweene white and blew, and speaking of the properties of them both, he saith that the *Methel* is cold in the fourth degree, so that if two drams be taken inwardly it killeth, if a lesser quantity it causeth a kinde of stupefying like drunkennesse: and of the *Vomica*, he saith onely that two drammes thereof taken with a decoction of dill, or with salt, doth marvellously provoke vomit, but giveth no deadly quality unto it, as he doth to the *Methel*: whereby it is thought that his *Methel* is our *Vomica*, and that his assimilating it to Mandrake is rather to be understood of the quality then of the forme, whereunto it answereth, but *Avicen* describeth the *Nux Methel* to have short and thicke prickles upon it, and a seed like unto Mandrake; and such indeed is the *Stramonium* so; that you may plainely see that *Serapio* confoundeth both these together, both for forme and property: and is likely that he never saw either of them, and therefore the Physicians and Apothecaries were in former times as much mistaken in appointing the one for the other: both *pro & contra*: but now seeing that they are better knowne, and well distinguished in sunder, they are used each according to their property: yet because

*Nux Vomica.* The Vomitting nut.

the

the fruite or nuts are not usuall in our shoppes, but hath beene formerly appointed to bee put into Antidotes and *Alexipharmica's* (as namely into the *Electuarium de Ovo*, according to the Phisitions of *Augusta* their receipt: but for their dangerous qualitie thought fit by our Phisitions in the *Pharmacopæa Londinensis* to be expunged and left out) I thought good to shew you them and the uses they are put to for the most part with us: The fruit, as is generally seene are flat, round, of the thicknesse of halfe ones finger, almost like unto Lupines but greater, hollowish on the one side, and a little bunched round on the contrary, of a grayish colour with a kinde of Freese or soft Cotten covering the whole, and of so hard a horny substance that they will no way bee beaten into pouther, but must be grated on a small Spice grater, but take heed not to grate Spice thereon after. The chiefest use that they are put unto is to kill Dogs and Cats, and other creatures, by mixing some of it with their meate; as also to give unto Crowes, Ravens, and other such like troublesome birds that by their noyse disquiet mens sleepe or studies, or upon pleasure to strew thereof upon flesh, a little sprinkled over with *Aquavitæ*, tied fast to some stake or other such like thing, which will make them after they have eaten thereof seeme as it were drunke for a time, tumbling off from the poast or tree upon the ground, there fluttering for a while untill the operation is past and then they will flye away. Some that give it inwardly three or foure graines at a time say that it expelleth pestilentiall vapours from the heart, and procureth sweate but not vomit as farre as I can learne, notwithstanding the name, and therefore *Matthiolus* would have it called *Nux Canina* rather then *Vomica*.

## CHAP. XLV.

### *Olibanum sive Thus.* White Frankumscense.

THe generall tenet both of old or ancient and new writers is, that the Francumscence tree doth grow in *Arabia*, yet *Dioscorides* saith in *India*, but *Garcias* saith none groweth there; and as some say, the Mirrhe and Frankumsence grow in the woods promiscuously together, but the description of the tree in particular was kept close (as it was anciently related) religiously by those that gathered the Gum, but those no doubt were but meere fables and tales to hold it in estimation, as that of the religious *Assirian* youth, slaine through envy, and therefore *Thus* the more accepted by the gods; for since the rites of Gentilisme here ceased, and Turcisme crept in place, the knowledge thereof by accesse unto places is as hard now as before, onely *Theophrastus* saith the leaves are like Bay leaves: but *Thevet* maketh it like the Pine tree, and *Garcias* saith that it is a low tree with leaves like the Masticke tree, and that the Gum of the mountaine sort is the best, and lastly, *Lobel* and *Pena* in their *Adversaria* give us the figure of a strange leafe to bee the leafe of this tree which consisteth of a double fould from the lower end, where it is small and pointed, to the toppe being broad and wide, like unto a Funnell, having as it were a small flippet or peece hanging down, which of all others is the most unlikly to be the leafe of this tree, the forme being of such an extraordinary likenes, and may more likely be the leafe of *Clusius* his *Limonio conger*, as I have before shewed you. I have therfore here given you the figure of the tree as *Lugdunensis* setteth it forth. Some have thought that the bark of this tree may be the *Narcaphthum* (which as some say should be rather *Nascaphthum*) of *Dioscorides*, and called *Thus Indæum*, for the Iews use it as Incense, and to such uses *Dioscorides* saith it was applyed, and for the Mother in women. The Gum droppeth from the tree in reasonable plentie into round peeces, some bigger and lesser then others, and scarce any exceeding the end of ones thumbe, the best is pure, without eyther barke, wood or any other thing, white, yea and the whiter the better, reasonable gummy or fat, not dry like Rossin, and consuming quickly and wholly into smoake. It is hot in the second degree and dry in the first and binding withall. It restraineth bleedings, stoppeth the laske and the Gonorrhea, helpeth the memory, avoideth sadnesse and melancholly, and comforteth the heart mixed with other things for that cause; it is also very pectorall and good for the cough, for thinne rheumes and distillations, and the Plurisie also, mixed with conserve of Roses and taken fasting, the fumes thereof when it is burned, being taken in at the mouth and nose, the head being covered is very availeable both for the Cough of the Lungs, and those thinne distillations thereon causing it: the fumes thereof taken beneath, or the application of it in ointment, helpeth the Piles and the *Tenasmus*, which is a disease provoking one often to the stoole without doing any thing, it is a singular good medecine for the rednesse and paines in the eyes, or in the eares: Mirrhe and *Olibanum* mixed with the white of an egge being beaten and laid on the temples helpeth the Megrome and paines in the head: it is of especiall use and account in Balmes, Salves, Plaisters, and Ointments for wounds and Vlcers, after their clensing to incarnate and heale them speedily, and in fractures of the skull most effectually, so that the *pia mater* be not perished. The barke

*Arbor Thurifera.*
The *Olibanum*, or Incense tree.

of

of the tree was in former times in much use by the ancients but is utterly neglected now a dayes which was more drying and binding then the Gum it selfe: they had also *Manna Thuris*, which some tooke to be a sort of that dewy Manna that is gathered from trees but were deceived, for it is but the small peeces of pouther of the *Olibanum* which is broken by the carriage: they used also the *fuligo* or soote of it when it was burned being made as blacking for shooes, &c. is made, but is wholly out of use now adayes.

## CHAP. XLVI.

*Piper ejusque species nigrum album longum, &c.* Divers sorts of Pepper, as blacke, white and long, &c.

HOw *fabulous* and untrue were the relations of *Indian* Drugs brought to the ancient writers, *Dioscorides* and others may be plainely discerned, by their description of the plant of Pepper, and the fruit thereof, for *Dioscorides* saith of it, that it groweth on a small tree, and that the fruit at the first is long, which is the long Pepper, having within it small graines like unto Millet seede, which in time growing ripe becommeth blacke Pepper, by spreading forth the branches and the graines of Pepper upon them as they are seene: and that the white Pepper is taken before it is ripe, the roote is like unto the *Costus* and not to *Ginger* as some say, thus farre he: but the truth is farre otherwise: for Pepper, whether blacke or white differeth not either in manner of growing, nor in forme of leafe or fruite; the long also groweth after the same manner, but differeth in the fruit: now all the sorts are sufficiently knowne by our Navigations and frequent transficke into the East *Indies*, to grow each on a severall climing bush, but after one manner, that is, as Hoppes doe with us, so that if they be not sustained by some tree, pole, cane or the like, whereon they may clime and spread, will lye downe on the ground, and thereon runne and shoot forth small fibres at every joynt, as hath beene truely observed: but the usuall manner is to plant a branch taken from the bush, neare unto some tall and great tree, or as I said some great Cane or such like, and so it will quickly by winding it selfe about it (but not with tendrells as a Vine doth) get to the very toppe thereof, being full of joynts, and shooting forth faire and somewhat large leaves one at a joynt, being almost round, but ending in a point, greener above and paler underneath, with a great middle ribbe, and foure other ribes somewhat lesser, spreading from it two on each side, and smaller veines therein also unto the edges which are not dented but smooth and plaine, not thicke but somewhat thinne, and set on a pretty long footstalke, the fruit or Pepper it selfe, whether blacke, white, or long, groweth at the same joynt, but on the contrary side opposite to the leafe, and not betweene the stalke and the leafe, as some have falsly set it downe round about a long stalke, somewhat thinly set all along thereon, or not so thicke as a bunch of Grapes: the roote hath sundry joynts creeping in the ground with fibres at the joynts, the white Pepper is very hardly

*Piper nigram vel album.*
Blacke or white Pepper.

*Piperis albi racemus.*
A branch of white Pepper.

distinguished

distinguished from the blacke by the very inhabitants and planters thereof, untill it come to ripenesse (for the white and the blacke Pepper doe grow on severall trees or bushes) but that the leaves are of a little paler greene colour: the graines or berries are white, solid, or firme without wrincles, and more aromaticall. *Clusius* first and *Bauhinus* from him would make a certaine strange fruit brought to *Clusius* to be the *Brasma* or *Brasma* of *Dioscorides*, as *Lib. exot. 2. cap. 22. fruct. 4.* but surely *Clusius* and *Bauhinus*, yea and *Cordus* also as I verily thinke were deceived in this their opinions, to thinke that *Dioscorides Brasma* was a sort of Pepper differing from the blacke, when as it is but the light graines of Pepper that have no substance in them, as it happens to many other graines or berries, some to idle and nothing worth, and therefore wee call it light Pepper. The long Pepper hath leaves very neare to the same forme and largenesse, but a little longer pointed, of a paler greene colour, thinner also, and with a shorter footstalke, and not having foure so eminent ribs passing from the middle one, as in the other, but foure or five on each side or more sometimes according to the largenesse of the leafe, with many other smaller veines therein likewise, and of little lesse acrimony and hot taste then the blacke: the fruite of this also groweth in the same manner as I sayd before opposite to each leafe at the joynts, which are closer set together then in the blacke, some being greater or lesser, shorter or longer then others, yet none thicker or longer then ones finger, consisting of many small graines as it were set close together in rowes, and not open and seperate as in the blacke and white Pepper, of an ash colour when it is ripe

*Piper Longum.* Long Pepper. *Fructus Piper longum.*

*Piper Æthiopicum Matthioli & Piper candatum Orientale: Matthiolus* his Ethiopian Pepper, and a kind of East India fruite called Pepper with a taile.

*Piper longum maritimum Africanum sive Felfel cavil Alpino.* Long Pepper of *Africa.*

as is plainely seene in all that is brought unto us. The blacke Pepper is of much use both with the *Indians* and other nations for they use to eate the leaves, chawing them a while and spitting them out againe and the Pepper it selfe also doe they use to chew, and from the branch take every graine one after another while they are fresh and therein take great pleasure, we use it most in our meats and sauces to season them, and because it is moderatly hot, if not taken too much at once, it is the better accepted and more pleasing to warme the cold stomacke, and to stirre up an appetite and to consume crude and moist humours therein, or distilling from the head; it helpeth to breake and dissolve winde in the stomacke or bowels, to provoke urine, to helpe the cough and other diseases of the breast, and is effectuall against the bitings of Serpents and other poisons, and is therefore put into the great Antidots: but the white Pepper as being more hot, sharpe, and aromaticall is of more effect in medicines, and so is the long also being more used to be given for Agues to warme the stomacke before the accesse or comming thereof, thereby to abate the rigour and shaking; all of them are used against the Quinsie being mixed with hony, and taken inwardly as well as applyed outwardly, and disperseth the kernells as well in the throate as in any other part of the body. *Matthiolus* maketh mention of a kinde of Pepper, as he called it *Piper Æthiopium*, or *Æthiopicum* brought with other wares from *Alexandria* into *Italy*, and groweth in long cods like beanes or pease, but many cods set together at a place, whose graines within them being like Pepper both in forme and taste, but smaller, and sticke very close to the inside: this sort *Serapio* setteth downe by the name of *Granum Zelin*, which some erroniously tooke for *Carpesium* and some for *Amomum*. *Monardus* also maketh mention of a kinde of long Pepper that groweth in all the tract of the continent of the West Indies which is halfe a foot long, and of the thicknesse of a small rope consisting of many rowes of small graines set close together as in the head of Plantane and is blacke being ripe, and hotter in taste, more aromaticall and more pleasant and sweet then *Capsicum*, and preferred before blacke Pepper, it groweth saith he on high trees or plants.

*Piper Æthiopicum Matthio.*

*Piper longum Occidentale Monardi.*

*Piper longum maritimum Africanum sive Felfel tauil Alpino.* Long Pepper of *Africa*.

This strange plant shooteh from the roote a great many low round stalkes somewhat like unto Rushes, having here and there some other smaller springing from them, like branches almost as thick as a finger, having thereon a few small leaves in the Spring time, but quickly falling away, scarcely abiding a moneth, and at the tops of some of them come forth small whitish flowers, each standing in a small long huske, in which after groweth the seed, the stalkes being cut or broken, yeeld out a whitish yellow milke or juyce, of a very hot and burning taste, more then ordinary Pepper, *Ranunculus*, or *Tithymall*, which caused *Imperatus* to referre it to the *Tithymals*. Yet some tooke it to be *Xabra*, or *Camarrones* of *Rhasis*, *Bauhinus* calleth it *Piper longum angustifolium ex Florida*.

*Piper Candatum racemosum.* Pepper with a taile in bunches.

About the yeare 1590. there was brought to *Lisbborne* by the *Portugale*, from some parts of the East Indies, which afterwards wee understood to bee *Guinney*, a kinde of graine, which they called *Pimenta del rabo*, that is Pepper with a taile, and grew many together on a long stalke, thicker set then in the ordinary Pepper, every one by it selfe on a short footestalke, being blackish, round, and firme like Pepper, with a little point or end, wherein it chiefely differed from blacke Pepper, and tasting hot, somewhat like Pepper, but of a sharper and differing aromaticall rellish, and a little lesse then the best sort of Pepper, but with a rugged skinne thereon like it, whether it grew after the same manner of Pepper, none could tell that brought it, but as it is probable by the sight of some of the stalkes, they seemed rather to grow from some upright bush. The King of *Portugall* forbad the bringing home any more of that sort, lest it should villefie the other.

*Piper Canarinum cavum.* A hollow kinde of Pepper of *Canara*.

*Garcias ab Orta*, maketh mention of this kinde of Pepper, which in the *Malabar* language is termed of *Canara*. It is a kind of hollow graine, of a blewish colour on the outside, and having sundry graines within the hollownesse thereof, which the poorer sort of people doe eate, and therefore as it is thought called *Canarinum* as if you should say Rusticall or Clownes Pepper for the meaneneesse thereof. and therefore not used to be exported.

## CHAP. XLVII.

*Santalum album, citrinum & rubrum.* White, yellow, and red Sanders.

WE have in our shops for our use in physicke, onely these three sorts of Saunders, whereof the white and the yellow are sweet woods, and the yellow is the sweetest, the red hath no sent. The Saunders tree, as *Garcias* saith, groweth to be as bigge as the Wallnut tree, having fresh greene leaves like unto the Masticke tree, and darkish blew flowers, the fruite being like unto Cherries for the size, but without any taste, blacke when they are ripe, and quickely falling away, the wood it selfe is without sent, as it is said, while it is living, and fresh, and smelleth sweete onely when it is dry, the white and the yellow woods, are so hard to be distinguished before that time, as it is said, that none but those Indians that usually fell those trees, doe know their difference before hand, and can tell which will prove better then others: the chiefest part, and smelling sweetest being the heart of the wood, and as the trees doe grow in severall places, so are their goodnesse, being more or lesse plentifull in the substance of the heart, for thereafter are they accounted: The ancient *Græcians* have made no mention hereof, but the *Arabians* onely, who generally call it *Sandal*, but the Natives in the Island *Timor*, and all the Provinces of *Malacca*, *Chandama*, and those of *Canara*, *Decan*, and *Surrat*, *Sercanda*; the Latines call that sort *pallidum*, which others call *Citrinum* from *Avicen*, who reckoning three sorts, *Citrinum Rubrum & Citrinnum alterum ve gens ad albedinem quod quidam nominant Makassari quod alij dicunt melius & validus*, which words in *Avicen* explaine the word *Makassari* which *Garcias* saith he could not understand, and the *Pandectarij* converted *odoriferum*: they of *Malabar* have a certaine sweete wood like unto white Saunders (as there are many other sweete woods in other places) but yet is not the right, although they use it as the true is, and instead thereof, calling it *Sambarane* in the *Malabar* language. The red Saunders differeth much from both the former, both in place growing farre one from another, and in forme, also colour and sent: it differeth also from the Brassill wood, in that Saunders is neither

sweete in taste, nor giveth any Dye as the Brassill doth, and besides, the Saunders is heavier then it, and will sinke in water, it is also a harder and shorter grained wood, and more brittle in breaking short. They are all both cooling and cordiall, and used together in sundry cordiall medicines, but the white, and the yellow are the more cordiall and comfortable by reason of their sweetenesse, and the red more cooling and binding, which quality yet neither of the other want, although in a lesse proportion, for the red is used often to stay defluxions of thinne rheume from the head, and to coole hot inflammations, hot gouts, and in hot agues, to coole and temper the heat: but the white and yellow are both cordiall and cephalicall, applyed with Rosewater to the temples, procuring ease in the head ache, and are singular good for weake and fainting stomackes, through heate: in the hot fits of agues also, they are very profitably applyed in Epithemes or Fomentations, both for the stomacke, and for the spirits, and palpitations of the heart, which also doe comfort and strengthen them, temperate the melancholly humour, and procureth alacrity and mirth, which qualities are attributed to the yellow more then the white, which is used more to stay and binde fluxes of the sperme in man or woman, for which purpose, either the pouther taken in a reare egge or mixed with other things for the purpose, or steeped in red Wine, and kept in an hot Balneo, or in hot embers close stopped all night, and strained forth and drunke in the morning and evening, both stayeth the Gonorrhea, or running of the reines in men, and the whites in women: applyed also to Maides or womens great brests, mixed with the juyce of Purslane, abateth their greatnesse, and represseth their overmuch growing.

## CHAP. XLVIII.

*Pseudosantalus Cretica Abolicea dicta.*
Bastard red Saunders of *Candy*.

THis tree groweth in *Candy*, and made knowne to *Alpinus*, whose figure was sent him as I here shew it you, with this description following. It is a tree that groweth to a reasonable great height, & straight upright, furnished with many armes and branches, very beautifull to behold, set with faire greene leaves one at a place, like unto those of *Alaternus*, but rounder and deeplier endented about the edges: the flowers were not observed what forme or colour they bore; but the fruite was round, and of the biggenesse of Pepper cornes, of a darke greenish colour which were not perfectly ripe, when this tree was found. The wood it selfe is somewhat sweete, hard, and reddish so that it seemed like red Saunders especially being made into pouther from whence I thinke saith he, it may not unfitly be called Bastard red Saunders of *Candy*, some of the wood saith *Pona*, hath beene brought into *Italy*, and there sold for Saunders: but it differs from it in that it is nothing so heavy as the true red Saunders is.

*Pseudosantalus Cretica Abolicea dicta.*
Bastard red Saunders of *Candy*.

## CHAP. XLIX.

*Sassaphras.* The Sassafras or Ague tree.

THe first knowledge of this Sassafras or Ague tree came by the *French* to our Christian world, and to the *Spaniards* by driving out the *French*, who had seated themselves somewhat neere the *Florida*, which they claimed for themselves for they having gotten Agues, and swellings in their legges, and other diseases by lying on the ground in the open aire by bad victualls and raw drinke of water, as the *French* before them had, by a *French* man that remained among them, were taught the use of this tree, which he and his Country men had learned before of the Natives,

to

to helpe themselves in these extremities: some Indians call the tree *Pavame*, and some *Winanke*: but the *French* (whom the *Spaniards* and all other Nations since that use it follow) *Sassafras*, upon what ground or cause is not knowne. The tree groweth great and tall, bare of branches unto a reasonable height covered with a grayish browne barke somewhat thicke, being in taste hotter and quicker then the wood or roote by much: towards the toppe it spreadeth forth many goodly armes and branches into a round compasse or forme, having large darke greene leaves growing thereon one at a place: standing on the contrary side, each to other, tasting like the roote but more weakely, some cut into three divisions, somewhat resembling Figge tree leaves, but lesser by the halfe for the most part, with a middle ribbe running through each division, and two others to the inner cuts, with veines besides, and some with little or no division at all upon them, for both sorts wee have seene growing on the same tree, smooth also and not dented about the edges: the flowers are small and yellow made of threds very like to the Male Cornel tree as Master *Iohn Tradescant* saith and the fruite small blackish berries, set in small cups upon long footestalkes many clustring together: the rootes are not very great nor grow deepe, in the like manner as all other sorts of Indian trees doe, but are covered with the like brownish barke, that the trunke and branches are but somewhat redder, which are most in use, being of greater force and efficacy then any other part of the tree, and taste somewhat spicelike, rellishing Fennell seede withall, but *Clusius* compareth the taste thereof unto the herbe *Tarragon*, and is hot and dry in the beginning of the third degree. The decoction whereof is familiarly given in all cold diseases and obstructions of the Liver and spleene, as also in cold rheumes and defluxions of the head, on the teeth, eyes, or lunges, warming and drying up the moisture, and strengthning the parts afterwards, and therefore is availeable in coughes, and other cold diseases of the brest, stomacke, and lungs, and restraineth castings, and helpeth digestion, breaketh and expelleth winde, the gravell and stone in the kidneyes, and provoketh urine, and womens courses, it also warmeth, heateth, and dryeth up the moisture of womens wombes, which is in most the cause of barrennesse, and causeth them to be the more apt to conceive: it is of especiall good use in tertian and quotidian agues that come of humours, or are of long continuance: it is thought also to be good in the time of the pestilence, to weare some thereof continually about them, that the smell of it may expell the corrupt and evil vapours of the pestilence: it is generally used in all the diseases that come of cold and raw, thin, and corrupt humours, the *French* disease, and other of the like foule nature: the Indians use the leaves being bruised to heale their wounds, and sores of whatsoever quality they be.

*Sassafras.* The Sassaphras or Ague tree

## CHAP. L.

### *Spermaceti.* Parmasitty.

SPermaceti, that is the spawne of the Whale, usually called in *English* Parmasitty, is found in the head of one onely sort of Whale fish called *Trumpa*, which hath no finnes in his mouth, but teeth about a spanne long, and as thicke as ones wrist: it lyeth in a hole therein, as it were a Well, which is taken out and brought home, after their fishing for Whales, in barrels, and is afterwards pressed in a presse, that the thinne oyle may runne from the thicker substance, which is that Parmasitty we use, and the more it is pressed the whiter it will be, and of little or no smell, yet the oyle is somewhat strong: this sort of Whale hath but one hole in the head, whereby it spouteth out water, all other sorts having two, his head is bigger then others, and bigger then his whole body besides, which is also of a more gray colour: in this Whales entralls, Ambergreise is said often to be found in more plenty then in other, which it is more likely that they swallow as food, finding it swimming on the Sea water, then that it should breed in them, as diverse have supposed, for I have here shewed you the generation of Ambergreese: this Whale also yeeldeth a kind of oyle, as other Whales doe, but it groweth both white and hard, when it is cold, when as all other are liquid like oyle, and never grow hard like it, and therefore it is alwayes kept by it selfe, and not put to others.

## CHAP. LI.

### *Tacamahaca.* The Gum Tacamahaca.

THis Gum, which the West Indians call *Tacamahaca*, the *Spaniards* and all other Nations retaining the same name, is said to be gathered from a great tree like unto a Poplar, that is, very sweete having a red fruite or berry like unto those of the *Peony*, more we cannot as yet learne of it. The Gumme is of good and much use for outward remedies, not being knowne to be given inwardly for any infirmity, although I doubt not but that it might safely and to good purpose, if judgement were joyned with the triall thereof, but as it is now generally used, it serveth much, yea and most of all in womens diseases to retaine the Mother in its place, by laying a plaister thereof upon the navell: as also when it riseth up and is ready to strangle them, and for the strengthening thereof, some put Muske and Amber to it, or a little Civet in the middle of the plaister: This Gumme being spread on leather and applyed to the side or spleene, that is growne hard and windy, dissolveth the tumours, disperseth the winde and bringeth much ease and helpe to the disquieted part, and is no lesse effectuall in all tumours, griefes, paines and torments in the body or joynts, proceeding of cold, raw, and windy humours, applyed plasterwise thereon: to be applyed to the stomacke, with a third part of *Storax*, a little Ambergriese, and some waxe, is a singular helpe to strengthen the weakenesse thereof to helpe digestion, to provoke the appetite, and to dissolve wind: it is of excellent use in the head-ache, and to strengthen the braine and memory, as also in all defluxions from the head, into the face, eyes, eares or teeth, causing swellings therein, with paines, rednesse, and much perplexity, to be applyed to the temples, or put into the eare, tyed in a little fine silke or cloath: it helpeth also all running humours, and paines thereby in the shoulders or armes, or any other part of the body, the joynts likewise, goutes and Sciatica, giving besides the scattering of the humours, much ease of the paines, and by the astriction whereof it partaketh not a little, strengtheneth the parts wonderfully against the virulency of the humours: it maryellously helpeth all punctures and wounds in the joynts, and that speedily, healing them and hindering any spasme or convulsion that may happen therein, so that this gumme serveth as a remedy in most outward griefes that doe not rise from much heate, and yet therein is not defective, being warily applyed, that is in the declination of the heate to discusse those humours that remaine: for being hot to the entrance of the third degree and dry in the second, with much astriction also, it is most proper for those before recited griefes, and others of the like property. The choyse of the best is, that it be pure and cleane without drosse, cleare also, in some sort of a whitish browne colour, and more whitish in some parts, of no strong but a little quicke and sharpe sent, and quickely consuming into smoake being cast on quicke coales.

## CHAP. LII.

### *Terra Lemnia vel sigillata.* *Terra sigillata* or sealed earth.

BEcause this is, and hath beene a drugge of much respect and use in physicke, although no herbe, I could not over passe it, but shew you the thing, and the many doubts and falsifications with the uses thereof, that my Brethren in profession, and all others also that shall have occasion to use it, may both know the right and refuse the counterfet and false: for that is the whole scope of my labours in this Worke, *viz.* to enforme all of the genuine and right things, that they may desire, and know them, and also the best true uses whereunto they serve. First for the Place it is certainely agreed by all, that the Isle of *Lemnos* seated in the *Ægean* Sea, called by the *Italians* and others in these dayes *Stalimene*, was in all former ages and yet is in these times, the place where onely this earth is to be had, which hath beene and still is of much estimation in physicke, for the excellent Vertues therein above all the earthes in all other places, and therefore the severall ages had severall rites whereby to ennoble it the more: *Dioscorides* saith of his time that they used to mixe the blood of a Goate with the earth, which *Galen* in his time (which was long after *Dioscorides*) being desirous to know, and what proportion of blood was put to the earth, he sailed twice to *Lemnos* for that purpose, but missing of the place the first time, at the second he came both to see the place from whence it was taken, and the manner of ordering of it, which was differing from *Dioscorides* his relation, for neither blood nor any thing else was mixed therewith, and *Galen* as he saith himselfe, was laughed at by the people of the better sort, who well understood the course of their Country for many foregoing ages, for asking such a question of the mixing of Goates blood with it: but the Priest that was then ready prepared to fetch home a cart full thereof, upon his arrivall there, onely cast a certaine number of Wheate and Barley cornes to the earth, as a pacification therewith, and some ceremonious rites, according to the Religion of his Country, caused it to be carryed home, where, having put it into water, they washed the pure earth from the stones and sand, or any other thing in it, which afterwards being dry againe, they make it into small cakes, some bigger or lesser then others, and seale them with the figure of a Goate, the badge of *Diana*: and therefore they were called *Sphragida ægios*, that is *sigillum capræ*, or *Sphragis Lemnia sigillum Lemnium*, and the La-

*Terra Lemnia vel Sigillata.*

tines

tines *Terra Lemnia* or *Terra sigillata*: Those rites of Gentilisme being ceased, others were brought in and used by the Christians, and when the *Venetians* were Lords of this Isle, as of many other in those Seas, they imposed this order, that but onely one day in a yeare the earth should be digged and carryed away to be used: Forbidding any upon great penalties to take any privily without leave: which custome the Turkes strictly observe to this day, but the hill in this Isle is much controverted, being suspected not to be the same from whence the earth was taken in *Galens* time, yet the Greekes of the Isle affirme constantly, they never heard or knew of any other place: The earth as *Galen* saith of it in his time, was called of some *Miltos Lemnia*, *Rubrica Lemnia*: because it was in colour reddish like *Rubrica* Ruddle, but that it did not colour the fingers, as *Rubrica* Ruddle doth, and this the Priest onely as is before said sealed: Another sort is the *Rubrica* which wee take to be our ordinary Bolearmoniacke, and some thinke that our finest and best Orientall Bole, is the true *Terra Lemnia*, because it is of the same reddish colour, not tainting the fingers, and that the *Terra Lemnia* or *sigillata*, that we have in these times much differeth from it, and very divers in it selfe one unto another, for some is whitish or very pale red, and that in lumpes or peeces not sealed, others that are sealed now adayes with *Arabian* Characters, which are interpreted *Tin imachton*, that is *Terra sigillata*, are not without some doubt of counterfetting, so that of two and twenty sorts of these small cakes of sealed earth, which *Bellonius* saith he had sought out and gotten in the shops of the Druggists in *Constantinople*, it was hard to judge which of them, or whether any of them were right or no, for as he saith, some cakes were much greater then others, and some of a pale brownish colour, of a fatty substance like tallow, easie to be chewed, and without any grittinesse therein, which some others have, that were more red, and somewhat acide in taste: Some againe had divers red spots in a whitish earth; and some smell so sweete that it may be thought to be so made; And some againe of a wan colour, tending to yellow, others very gritty betweene the teeth being chewed: these and divers other varieties, doe shew that covetousnesse (this being of much esteeme) is the cause of counterfetting, and besides experience sheweth us, that the earthes of sundry other Countries are found to be of excellent properties, both to provoke sweate, to resist poyson, and notably to dry and bind fluxes, catarrhes, &c. all which are attributed to the best *Terra Lemnia*, but *Galen* in his time had the tryall of the *Bolus*, or *Terra*, or *Lapis Armenius*, which you please to call it, for sundry especiall remedies wherein it was effectuall, as also in a great Plague time in *Rome*, which he compared to that was in *Greece* in *Thucydides* time, for as he saith, whosoever tooke of that *Bolus Armenius*, dissolved in thinne wine or water, were saved if they were to be saved, for no other thing could if that did not: and therefore seeing we have so little right *Terra Lemnia* or *sigillata* wherein to trust, and so much counterfet, whereof we have cause to beware, my advise is rather to use the best fine Bole (which both in forme and quality commeth neerest to the truest *Terra Lemnia*,) then any other substitute or new found earth, going under the name of the right, although they have divers good properties in them. Let no man impute this as a temerity in me, for could I be assured that we could have true *Terra Lemnia*, or that the true that now is to be had were of that excellency that *Dioscorides*, *Galen* and others report of that in their times, I would spare my advise and speake otherwise. But seeing I have commended the fine Bole for the best substitute unto *Terra Lemnia*, let me also declare unto you, although I have said somewhat before of Bole, the speciall uses of both of them, that by comparing their properties, you may see how little they differ in quality: The chiefest effect of *Terra Lemnia*, according to *Dioscorides*, is to resist the venome of Serpents, and other deadly poysons, for which cause it is put into the great Antidotes against them, and is good also against laskes and fluxes: but *Galen* setteth them forth more largely, for as he saith, having had a Booke given him when he was in the Isle of *Lemnos*, by one of the chiefest men, containing all the properties of *Terra Lemnia*, he sheweth that besides the remedies of venome and deadly poysons, he had experience of the helpe it gave to those that had eaten of the Sea Hare, or of *Cantharides*, defending them from all the fits that doe accompany those that have taken of them, as also the biting of a mad dog, and that it wonderfully helpeth old sores that are hard to be cured, and fresh wounds also to consolidate them. The fine Bole of *Armenia*, *Galen* sheweth to be admirable effectuall in the plague, as is before said, it also is singular good in laskes, blooddy flixes, and spitting of blood, for the catarrhe, or desluxion of rheume and thinne humours upon the brest and lungs, and shortnesse of breath, marvellously drying and helping them, and likewise against the foule ulcers in the mouth, the ulcers in the lungs or other parts, and the fistula in any, without applying any other thing that might clense it, or take away the callous skinne therein, this onely dryed it, and healed it up.

## CHAP. LIII.

### *Turbith officinarum.* The usuall Turbith.

HAving said something before in the Classis of purging Plants, concerning the various sorts of Turbith, as divers did take them, and account of them, whereof I meane not to speake againe in this place, but yet I thought good here, to say somewhat more of the true Turbith, which is a forraigne Drugge, and used in the Apothecaries shops, not knowne to us or any other certainely, that hath written thereof, what forme or face the plant truely beareth, whose roote it is: for although *Garcias* saith, that he saw the plant growing greene and in flower (yet he saith himselfe that it differeth from that which we use in our shoppes) which he describeth to have no great or long roote, whose stalke is like unto Ivy, spreading on the ground, of a fingers thickenesse or more, and two hands long, and some times much longer: the leaves are like unto those of the *Althæa*, Marsh Mallow, and so are the flowers of a reddish white, and sometimes all white, but not changing three times a day, as some report of it: that part of the stalke that is next unto the roote and is gummy, is onely used, the rest being too small is of no use: sometimes the roote is gathered with the stalke, which is unprofitable, the stalke onely being of use in Physicke: the whole is insipide without taste: so that you may perceive by this description, that this Turbith of *Garcias*, is but the stalke of an herbe as it seemeth (but our Turbith in shops is plainely deserned to be a roote, yet somewhat small, and of an ash-colour on the outside, and white within, having a pith in the middle, which is cut out and cast away as unprofitable,

profitable, and ſome peeces, but not all gummy at the ends having no manifeſt taſte) which by bruiſing of it while it is greene, as he ſaith, yeeldeth forth a juyce that hardeneth into a gumme; yet doth *Garcias* appropriate this Turbith in his following diſcourſe to that which was with them of daily uſe, ſaying that the *Arabians*, *Perſians*, and *Turkes* call it all by the name of Turbith, by the Indians in *Surrat*, where it groweth plentifully *Barcaman*, and in *Canara*, whereof *Goa* is a part *Tigmar*: It groweth alſo as he ſaith in other places of India naturally wilde: but that of *Biſnager* or *Goa*, is not uſed by the Phyſitions there, but that of *Guzatate*, which is the beſt, from whence alſo as he ſaith, it is tranſported into *Perſia*, *Arabia*, *Aſia minor* and *Portugall*. In this diſcourſe of *Garcias*, I finde ſome contrariety as I take it, at leaſt ſuch intricacy, as maketh me doubt it was not ſo adviſedly written, as ſo worthy a man (whoſe Workes and labours were as directions to poſterity) ſhould have done; for firſt he ſaith that the ſtalke is of uſe, the roote is unprofitable, and yet he ſaith this very ſame is both called Turbith, and uſed by the Phyſitions there, of all nations as the Turbith of the ancients, which that the Indians gather it to ſell to the Merchants, that carry it into their Countries, and yet it was never ſeene that any ſuch gummy ſtalkes were brought into theſe parts of Chriſtendome that I can learne, and ſold by the name of Turbith. Againe, *Garcias* ſaith that this his Turbith is farre differing from that which the *Arabians* deſcribe, and namely that of *Meſues*, which he deſcribeth with thoſe notes that are moſt agreeable unto that Turbith that is every where to be found in all our ſhops, and yet *Garcias* taxeth him of erronious deſcribing of it, as though thoſe notes did not agree to the true Turbith that is brought out of the Eaſt Indies, by the *Portugalls*, into Chriſtendome, when as we never ſaw any other brought from thence, ſo that I cannot ſee how *Garcias* can be freed from the imputation of much overſight, that tooke his Turbith to be the ſtalkes, and not the rootes of the Turbith plant: for I verily thinke his Turbith and ours to be all one, and that his errour roſe onely from being too confident on his Kinſmans relation thereof, to be the ſtalkes, who as he ſaith, informed him of the plant, the manner of the gathering and uſage thereof by the Indians, and that himſelfe was preſent with the Indians, and ſaw the whole ordering of it, and is probable was but his owne conceit and fained to make *Garcias* beleeve it: for how elſe could that be differing from that of *Meſues*, which verily is the ſame with that, which as I thinke hath beene alwaies brought us for Turbith, and yet be the ſame the *Portugals* brought with them from thence, to ſerve all Chriſtendome. The notes of *Meſues* his Turbith, which as I ſaid agree ſo juſtly with our Turbith, that you may know how to chuſe the beſt are theſe; but firſt he ſaith that it is the roote of an herbe, which hath Ferula like leaves but leſſe (which how true it is I cannot ſay, *Meſues* peradventure never having ſeene the plant growing, giveth that note rather by information, which *Garcias* it may be ſheweth by his owne ſight but of the roote, which ſerved him for his daily uſe, he was an eye-witneſſe and teſtifyeth of it) and was of the kind of thoſe plants that give milke (and yet not of any Tithymall for divers other plants give milke that are not hot in taſte as the Tithymalls) and was of divers ſorts, manured, and wild, great, ſmall, white, blacke, and yellow, and growing in dry places as may be perceived by the thickeneſſe of the juyce (the gummineſſe he meaneth) and both greater and ſmaller rootes, white, and blackiſh, and yellow, are many times ſeene altogether with us (which blackneſſe or yellowneſſe may come by the ill drying of the roote, or the taking of ſome wet in the drying or after) he maketh two markes of the choyſeſt: that it be white (within) hollow within like a reed or cane (that is when the hard pith of the roote is taken out) gummy with an aſh-coloured barke or outſide, ſmooth, and not rugged, eaſie to be broken, freſh, and not very great or thicke, which is not ſo good, theſe notes doe all agree to our *Turbith officinarum*. Turbith is more uſed to be given in poudher, and that ſeldome alone but mixed with other things, or elſe made into an electuary, then in decoction, and purgeth flegme very notably, and tough clammy humours that fall on the joynts, or on thoſe parts that are more remote: it looſeneth the belly of thoſe excrements that ſticke cloſe thereto, and cleanſeth the breſt from thicke flegme: it is very profitably given to thoſe that have a dropſie, the leproſie, or the *French* diſeaſe, as alſo thoſe that are troubled with thoſe diſeaſes that riſe from aduſt humours, the blacke jaundiſe and the like, it helpeth day agues, and in generall all other diſeaſes bred of flegme,

*Turbith officinarum.* The uſuall Turbith.

CHA.

## CHAP. LIV.

*Vnicornu sive Cornu Monocerotis.* Vnicornes Horne.

VNicornes Horne likewise is a precious Iewell of high esteeme, and with Princes kept alwayes in their treasury to be used upon occasion for themselves, whose worth poore men could not easily reach or attaine unto. There are divers beasts that beare two hornes both male and female, as the Oxe, others the males onely, as Deere, Sheepe, &c. Some beare three hornes, as certaine Oxen in India, as *Solinus* reporteth, and some foure, as divers Rammes in sundry Countries hath beene observed, yet casually, not by kinde, and some againe beare but one, whereof some beare it on their nose, as the Rhinoceros, and some in their forehead, as the Indian wild Asse, with a whole hoofe as other Asses have, whereof *Aristoles* and *Pliny* speake, and *Orix* with a cloven hoofe, related by them also and *Columella*: as also certaine Kine in *Zeila*, a City in *Æthiopia*, and *Camphur*, a certaine beast plentifully breeding in the *Molucca* Islands, that liveth both in the water and on land. Some other creatures also there are that beare but one horne, as certaine Fishes, breeding plentifully in the Indian Seas, whereof *Vlerif* so called (which I take to be the Sea Vnicorne) is one, and the Sword fish, and certaine birds in *Æthiopia* as *Ælianus* maketh mention: but of all these creatures with one horne, none are said or found to have white hornes but the Vnicorne (of the Sea as well as the Land) called by the Hebrewes *Rem* and *Reem* (famoused in the Scriptures) by *Avicen Achercheden*, by some other *Arabians Barkaran*, by the Greekes *Monoceros*, and by the Latines *Vnicornus*, for some are said to be black e others red, *Ælianus* describeth the Indian Asse to have his horne to be whitish at the bottome, reddish at the toppe, and blacke in the middle: the received opinion of the Vnicorne is, that it is a beast of the size of a meane horse (but I thinke it cannot be possible but he must be much greater, to beare so large so long, and so massie a horne, such as are to be seene in sundry places of *Europe*, (if such be the horne of any beast) for as *Bellonius* saith there are twenty whole hornes, and as many that are not whole but broken, to be seene in severall places in *Europe*, one whereof which is the greatest and most noble, is that which is kept in the Church of Saint *Dennis* by *Paris*, which is seven foote long at the least, so that a tall man can hardly reach the toppe thereof with his hand, it weigheth 13. pound and foure ounces, no man can graspe it wholly in his hand, being five inches in the diameter or thickenesse, and an handbredth, and three inches in the circumference, it is straight like a torch or staffe, but writhed about on the outside, from the right hand to the left smooth, smooth and not bunched out, save at the lower end next unto the head, where it is greatest, and falling still smaller unto the end, of a brownish colour on the outside, but white like Ivory within, without any line in it, and having but a ring about the outside, it is also hollow at the bottome, a foote upwards, whereby it may plainely be discerned that it falleth not off of it owne accord, which maketh it to be of the more account) the beast is said to be of the colour of a Weasell, or somewhat more red (yet some say grayish) having a head like a Hart, the necke and maine not very long, with thinne haires, and falling to one side, with a small beard like a Goate but lesser and shorter, the thighes and legs, not great, the hoofe parted and the taile like a Boare: but none of the auncient Writers, have made mention of any Physicall properties therein, *Ælianus* onely accepted *lib.4. c. 52.* who yet saith the horne is blacke. The property of the Vnicornes horne is cheifly to resist poyson, and the bitings of venemous creatures, it is also given against the plague; and other contagious diseases, to expell melancholly likewise, and to cherish, exhilirate, and strengthen the vitall spirits, and more noble parts. It hath alwayes beene accounted of great worth, and not but for great persons and Princes, for the beast being rare and seldome to be seene or had, being so wilde and fierce that he is not to be made tame (howsoever some have written that they will grow milde at the sight of young Maidens, and be brought to sleepe neere unto them) and the hornes not to be had (in that they doe not cast them as some other beasts doe) but by the death of the beast, that liveth so farre remote from these parts, and in huge vast Wildernesses among other most fierce and wilde beasts, Tigers, and Panthers, &c. and especially, because the Indians hunt them not either for their pleasure, or to make any profit by them, the Merchants not seeking after them, the hornes I say, must needes be rare and scarce to be had, and of great worth and price, if they be had, which keepeth them in the more high esteeme. And therefore there want not Imposters, that for lucre sake, doe counterfet it, and worke Ivory, and other hornes artificially into peeces of severall shapes and formes, and obtrude them for Vnicornes horne, to many ignorant persons, but the true and right horne is in part described here before, but to adde further, that the true horne being broken, sheweth to have some thicke fouldes or coates one over another, the inside is white, though the outside is not so white but brownish, and a very smooth graine, without any line veine, or curled waving therein, having onely a circle sometimes about the edge or brimme. Much Vnicornes horne as they say, is to be had with our Druggists and Apothecaries, which is in small long round peeces, some no thicker then ones finger or thumbe at the most, or seldome bigger, that is very white, somewhat heavy and solid, with a smooth graine, which because I cannot thinke so much of the right Land Vnicornes horne is to be had so readily, and so small: I verily beleeve it to be of the Sea Vnicorne, which whether it hath that efficacy that the other is said to have I know not.

And it is somewhat probable that even all those hornes formerly mentioned both in *France*, *Venice*, or elsewhere, and that also of our Kings, kept at *Windsor*, or the Tower, is but of the Sea Vnicorne, for even such as is before described was brought home by Sir *Dudley Digges*, as I take it found on the shore, and cast up by the Sea in some place towards the North-West, and given to our King *Charles*, who for the tryall caused his Physitions and others to view it and make report thereof to him. And my selfe having seene it, did well perceive it to be writhed on the outside, in the manner before said, and was wonderous white within also, and of a close firme graine: The horne was not fully whole, but broken off a little at the end, and hollow at the bottome.

## CHAP. LV.

### *Zedoaria & Zerumbeth.* Setwall.

THe Setwall that we have usually in our shops, doth not alwayes hold one uniforme face and fashion, but divers, for some is thicke and short, others more long and round, some great, others small, some whole, others broken, as it is usuall in all things almost, either forraigne or domesticke, and yet the severall varieties of formes, being of so little difference cannot make them severall things, especially seeing their taste and quality is all one, or but so little differing that any judicious may soone determine the controversie. *Garcias ab Orta* distinguisheth betweene *Zedoaria* and *Zerumbet*, making them to be two divers things and therefore speaketh of them in two severall Chapters, wherein as it seemeth he maketh *Zedoaria* to be the *Geiduar* of *Avicen*, which yet he saith *Avicen* knew not, because it groweth in the *Chineses* Country, and is very rare to be seene or had, but from such vagabond Indians, called *Iogues*, as travaile begging through all those Countries, which *Geiduar* or *Gedwar*, as *Garcias* saith is of the bignesse of an Ackorne, and neere unto the same forme, weighing about halfe an ounce, and of a cleere colour, but *Clusius* giveth us the description and figure of it a little larger, which as he saith he had from *Pona* of *Verona*, and compareth them to the smaller rootes of *Asphodill*, or the rootes of *Anthora* of an ash-colour on the outside, and yellowish within, and of an hot sharpe taste. *Zedoaria* is called *Zurumbet* by *Serapio*, and saith they are rootes like unto the round *Aristolochia*, but of the colour and taste of Ginger, and brought from *China*: *Avicen* saith that *Zedoaria* is like unto *Aristolochia*, but lesser, and afterwards saith, that it is likely to be *Geiduar* or *Algeiduar*, and giveth unto it the same qualities that *Serapio* doth to his *Zedoaria* or *Zerumbet*: *Rhasis* maketh *Zedoria* and *Zerumbet* all one, and *Mesues* also seemeth to agree unto them, but differeth onely in a degree of heate; so that you may plainely see that all these sorts are made by these Authours to be of little or no difference, and so they seeme unto me, as they have also to others before me, who have as I have done, seene all these diversities of forme come over together unto us: *Lugdunensis* setteth downe very truely the figure of *Zedoaria* and *Zerumbet*, as they grow together, the longer peeces joyning to the round like the *Asphodill* rootes, to one round head. *Garcias ab Orta* saith, that *Zerumbet* (or *Zerumba*, although he maketh them differing as I said, in one Chapter, yet all one in the next) groweth plentifully wild in *Malavar Calecut*, and *Cananor*, and is also planted by divers in sundry places, calling it wild Ginger, those of *Surrat*, *Decan*, and *Canara* call it *Chachoran*, and those of *Malavar Sua*, and hath leaves like unto Ginger but greater, longer, and broader. There have beene some that have thought *Zedoaria* to be some of the kindes of *Costus* that *Dioscorides* describeth, because it agreeth in many things therewith, *Zedoaria* being not specified by him, or the auncient Greekes, and indeed both forme and quality comming so neere may cause it well to be accepted as the substitute thereof. All these sorts as they are made divers by the writers of them are said by them to be effectuall against poysons of all sorts, and venomes of virulent creatures, and we have found them of much use and profit in the pestilence and other contagious diseases, as also to warme a cold stomacke, and to expell winde mervailously, to represse vomitings, to dry up and consume catarrhes and defluxions of rheume, to dissolve the Impostumes of the matrix, and to stay the loosenesse of the belly, and is also very powerfull to stay or disperse the unsavoury belchings of those spirits that Garlicke, Onions, &c. or wine have caused.

*Zedoriæ longæ & rotundæ genuina effigies itemque & Geidwar Arabum.* The true figure of the long and round *Zeboaria*, and of the *Arabians Geid.var:*

## CHAP. LVI.

### *Zingiber.* Ginger.

GInger as *Garcias* saith groweth in all the Countries of the East Indies, either planted by the roote or sowne of seed, (the roote saith an *English* rare traveller, spreadeth in the ground, and hath leaves like wild Garlike, which they cut every fortnight, to put into their brothes and meates:) It groweth saith he, with leaves like the water Flagge, or Corne Flagge, and not like the Reed, thus saith he, and so saith *Monardus* also, but *Acosta* saith that it hath leaves very like to the greater sorts of Millet, *Iobs* teares, and with a thicke stalke like Asphodill leaves thereon, close to the stalke, so that it seemeth to be a small Reed, and *Lobel* setteth

*Zingiber forte Brasiliense nigra radice.*
Brassill Ginger with a blacke roote.

*Zingiberis siliqua & semen.*
The seed pod, and seed of Ginger.

*Zingiber orientale florescens.*
The figure of the orientall Ginger with the flower.

setteth forth the figure of Ginger as it grew he saith with *Adrian Meuleneere* in the Prince *Mauritius a Nassau* his Garden, having sundry stalkes about a foote high, shewing like unto a Reed new sprung up, and condemneth that old figure as false, that was formerly accounted the right, which had leaves of the fashion of an *Iris* or Flowerdeluce, which contrarieties are as some may thinke, hardly to be reconciled, yet I will endeavour to make both these assertions to be true although they seeme so much to vary, thus: We have two sorts of Ginger brought unto us, plainely differing in the substance and colour of the rootes, but not in the forme, saving that the one is more slender which is the blacker, then the white, for the one is white within and cutteth soft, which is the Ginger wholly in use for meates and medicines with us, the other is hard and almost wooddy, and cutteth blackish within, so that it is very likely that the one sort which I take to be the East Indie sort, with the soft white roote, hath Flagge-like leaves, and hath beene seene in flower in *Germany*, as *Emanuel Zwerts* hath set out the figure (and I here unto you, and the seed vessell also, with the seed not much unlike that of an *Iris*) with this title *Zinziber flore albo folio Iridis*. The other roote that is more slender and blacke, yet of the same fashion, may be that which beareth Reed-like leaves, as *Lobel* hath set it forth, rather to be preserved then for ordinary use with us, and which as I thinke is the *Mechinum* of *Lobel*, or *Zingiber fuscum*: whereof he giveth the figure of a more excellent sort, that was joynted like *Doronicum* parts, and therefore accounted by *Pona* to be the true *Doronicum*, as is shewed before in this worke, in the Chapter of *Doronicum*, and brought from *Brassill*: So that the matter being thus reconciled, and each of them sorted as they should be, let me shew you that both sorts are preserved while they are fresh and greene, and the blacke sort as well also, after it hath beene dryed, by new steeping it, and boyling to make it tender, but I cannot finde that the white sort will so well serve to be preserved after it hath beene dryed, but is the best being preserved greene, such as the *China* and *Bengala* Ginger is. The properties of Ginger is to warme a cold stomacke, and to helpe disgestion, to dissolve

dissolve wind both there and in the bowels, while it is fresh it is eaten in sallets with the Indians, the roote being sliced and put among the herbes, and helpeth to mollefie and loosen the belly by the moisture therein, which then abateth much of the heate which being dry it hath, and helpeth to bind the belly. The preserved Ginger is most acceptable and comfortable to the stomacke, and is availeable to all the purposes aforesaid.

## CHAP. LVII.

### *Zibettum.* Civet.

Ivet, called *Algalia* by the Indians, and the beast from whence it is taken *Algali* or *Aligali*, is well knowne now adayes to all, to be an excrementitious moisture, or condensate sweate of a certaine beast somewhat like unto a great Cat, and thereon called a Civet Cat, gathered from a peculiar place or purse in that Cat, prepared by nature for that speciall purpose, and is taken forth with small spoones of Ivory or wood, and that by strong hand, the beast being held very close and hard for feare of biting, while they are in taking it forth, for it is very fell and fierce, being moved and angered, and then most when they are about that businesse. I shall not need to describe the beast unto you, which *Clusius* hath done in figure very exactly in his *Curæ Posteriores*, and is so frequent, not onely in our Land, with a great many that keepe them for the profit or use of the Civet, but in divers other Countries in *Europe*. The Civet is used as a perfume or sweete sent generally, either by it selfe or mixed with other sweete things, it is used also to comfort the head and braine, and to helpe the deafenesse and dissinesse in the eares, being put thereinto, wrapped in a little blacke wooll, it is much commended against the suffocations or rising of the mother, to be used in a plaister, or but put on the middle of the plaister and laid on the Navell, or some put into the Navell. I know none that ever used it inwardly, but in outward remedies: it is said that women are much delighted therewith, and helping sundry of their defects.

Having thus shewed you here most of the chiefest Drugges in our Apothecaries shops, that comē to us from forraigne parts, that are not formerly expressed in this Worke in severall places: Let me now lastly to close up this whole Worke, shew you other strange and rare Plants, both Herbes and Trees, with their Gummes, Seeds, Rootes, and Fruites, &c. growing in the East, and West Indies, and those parts neere unto them, as they have beene observed by those that in their travells saw them, and brought many of them into *Europe*, that wee may contemplate the wonderfull Workes of God, that hath stored those Countries with such differing Herbes and Trees from ours, and yet it is very certaine that there is much more unknowne then is already made knowne unto us. I will first beginne with Herbes, and the parts thereof, as seedes and rootes, whether medicinable or admirable, and then with the Trees and their fruites that are pleasant to eate; and lastly with those which for the most part have some medicinall use.

## CHAP. LVIII.

### *Payco herba.* Indian Plantaine for the stone.

There growethin *Peru* in the West Indies, an Herbe whose leaves are like unto our Plantaine, which being dryed are very thinne, and taste hot and extreame bitter. The pouther of them taken in Wine, helpeth the chollicke and the stone, whether proceeding of wind, or of any cold cause, the leaves boyled and applyed warme to the pained part, worketh the same effect.

*Herba ad renum morbis utilis. Lactucæ similis.*

Another Herbe likewise was sent from thence like unto Lettice new sprung up, and of the same colour, being without taste and very profitable for the stone in the kidneyes, comming from heate, the juyce being applyed to the place mixed with some oyntment of Roses, and the leaves also laid thereto: the juyce thereof likewise cooleth inflammations, Saint *Anthonyes* fire and the like hot eruptions in the skinne, and easeth the paines.

*Cackos semen.*

From *Peru* likewise saith *Monardus* came the seed of a bushy plant, there called *Cachos*, being very small and taken from the fruite thereof, which was like unto the *Mala insana*, Madde Appels, flat on the one part, and round on the other, of an ash colour on the outside, and of an excellent greene colour but thinne, and of a round forme. It is of much esteeme with the Natives, for the especiall vertues thereof, in provoking urine, and expelling gravell and the stone, yea and breaking the stone in the bladder, if it be not growne hard by long continuance, dissolving it into sand, and casting it forth with the urine, the seed in pouther being taken in some water convenient for the purpose, whereof they have had very many and notable experiences, which sand after it is expelled will grow hard as into stones againe.

## CHAP. LXIX.

### *Coca.* The herbe Coca.

The seed of this Coca is sownē with great care by the West Indians in beds, by rowes, and riseth to be a plant of three or foure foote high, with a stalke as bigge as a good wand, and somewhat greater leaves then the Myrtle, having as it were another leafe in the middle thereof, being soft, and of a pale greene colour: the berries are red before they be ripe, but blackish afterwards, growing clustring together, and then they gather the leaves, laying them to dry, that they may be kept all the yeare

and

and carryed to and fro into ſeverall Countries, for thereof is the Natives chiefe Merchandiſe to provide them of all neceſſaries for life, being inſtead of money, which is generally uſed by the *Americanes* to be chawed, as well in their long journeyes to preſerve them from hunger and thirſt abroad, as for pleaſure at home, which they uſe after this manner: they burne Oyſter ſhells, and with the powther of them they mixe the pouther of the leaves of this *Coca* firſt chewed in their mouthes, and ſo made up as it were into a paſte or dough (but take leſſe of the pouther of the Oyſter ſhells then of the leaves) whereof they make ſmall pellets *trochiſſes* or *troſſis*, laying them to dry, and ſo uſe them one by one, holding them in their mouthes, rolling them to and fro, and ſucking them untill they be quite ſpent, and then take another, which maketh them able to travaile many dayes with ſtrength, without either meate or drinke, through uninhabited places, where none is to be had: If they ſtay at home, they uſe the *Coca* alone, chewing them ſometimes a whole day without ceaſing, untill the ſubſtance be ſucked forth, and then uſe another; if they would have them to be ſtronger, able to intoxicate their braines like unto drunkenneſſe, or to be as it were ſenſleſſe, they put the leaves of Tobacco to it and take great pleaſure in thoſe courſes.

## CHAP. LX.

*Betre, Betle, Betele, ſive Bethle.* The Indian Bindweed called *Betle* or *Betre*.

THe Eaſt Indians doe uſe the leaves of this *Betle*, much after the ſame manner that they of the Weſt doe the laſt recited *Coca*, and therefore I thought good to joyne them together. It groweth very like unto a Bindweede, wrapping and winding it ſelfe about the trees, up to the toppes almoſt, or other things that it is planted againſt to uphold it, or lye on the ground and rot, and therefore they for the moſt part, plant it againſt the tree *Faufel* or *Areca*, or ſuch other like tall and great trees, in the ſame manner as they doe Pepper, whereunto it is ſo like that a farre off, thoſe that are not well exerciſed in the knowledge of them, may ſoone miſtake one for another (and therefore *Gerard* called it Baſtard Pepper, when as it is neither in fruite, taſte, or uſe like unto Pepper) having onely leaves ſomewhat like to Pepper, but more like unto Bindeweed, yet thicker, of a yellowiſh greene colour, with three great thicke ribbes therein (which the Indians with the nailes of their hands, kept long and pointed for this purpoſe and not round like ours, doe nippe or pare away before they dry them, whoſe taſte is ſomewhat aromaticall but bitter; the fruite is ſlender, and about two inches long, writhed or conſiſting of five cods writhed one about another like unto a cord or rope, of a yellowiſh colour, taſting pretty ſpicy or aromaticall, the plant is much tended and often watered to cauſe it grow the better, and becauſe it delighteth not in any very hot or cold Country, and ſeldome groweth in the upland Countries, but continually neere the Sea ſide, or not farre diſtant from it. Phyſically this is uſed to ſtrengthen the head and ſtomacke, after the clenſing of them from rheume and flegme, to comfort the heart, and to breake or diſcuſſe winde in the ſtomacke or bowels: it faſtneth looſe teeth, and maketh them yellow, cauſing alſo a ſweet breath, yet their breath ſtincketh fowleſt that uſing daily to take it, doe forbeare for a while from it: but generally throughout all the Eaſt Indies, the leaves are uſed both of the Princes and people, the greater perſons make certaine compoſitions for themſelves, with the leaves hereof, Camfire of *Burneo*, *Lignum* Aloes, Muske, and Ambergrieſe, others put Cardamomes, and Cloves to them, but the ordinary manner of preparing them is, that after the ribs be taken away with their nayles, they chew thoſe leaves in their mouthes, and ſpit out the firſt juyce that commeth from them, which is like blood, and put unto them a little of the *calx* of burnt Oyſterſhells, and the fruite of *Areca* or *Faufell* beaten ſmall which give them a pleaſant taſte, and is generally eaten by them all, and none of the meaner ſort or others that have not preſently before eaten thereof, will in civility ſpeake with any great perſon, but they will hold their mouthes that their breath doe not offend them. It is called *Betre* in *Malavar* and *Pam*, in *Decan* and *Guzarate* but in *Malayo Siri*, *Garcias* ſaith that he as well as others tooke theſe leaves to be the *Folium Indum*, or *Malabathrum* of the Greeke Authours; but was deceived therein.

*Betre ſive Betle.*
The Indian Bindeweed called *Betle* or *Betre*.

## CHAP. LXI.

*Guacatane. Indian* Pilewort.

THis small herbe as *Monardus* saith was sent out of that part of *America* or the West Indies that is called *Hispania nova* being white like unto *Polium montanum* but without any sweet sent, and is much commended to helpe the swelling and falling downe of the Piles or hemorrhodiall veines if the herbe be boyled in wine so as there be no heate, or else in water and the grieved place fomented with the warme decoction for a while then gently wiped and the pouther of the herbe cast thereon being bound thereunto: it also easeth aches and paines in any part of the body if the grieved place be first annointed with molten Rossin not too hot, and the pouther of the herbe strewed thereon (which is an homely manner of dressing) and cloathes layd presently upon it which will sticke so fast as that untill it hath wrought the effect it will not be plucked from the skinne and flesh: the pouther of this herbe cast upon any small wound or sore, especially those in the groine, doth clense them and heale them afterwards.

*Guacatane. Indian* Pilewort

## CHAP. LXII.

*Herba Indica ad rupturas utilis. Indian* Rupture-wort.

ANother small herbe was likewise sent from those parts, whose forme could not be discerned by reason of the ill carriage and breaking thereof being dry: but highly commended to helpe Ruptures or burstings in young or old: the herbe being fresh bruised and applied to the place whereunto a trusse afterwards was bound that had no shoulders, yet sate as close as those that had, and this *Ligaturo* the *Indians* use, which kind of trusse saith *Monardus* lying so firme and close as he reported that was cured thereby, is sufficient of it selfe to helpe any Rupture without any other medecine, and as he saith he saw a leech of *Corduba* that helped all burstings with such unshouldred trusses or bindings onely, and many hee knew then living that were so cured.

## CHAP. LXIII.

*Planta Indica sanguinalis Panacea, id est, sanguineos sudores excitans.*
The Indian Allheale, blood sweating plant.

A Certaine Indian Leech as it is recorded in *Petrus de Osma* his letter to *Monardus* did usually in the City *Pasto* cure all manner of diseases onely with the juice of a certaine herbe annointing the Arteries and the grieved place therewith, and afterwards laying them to sweate in their beds being well covered, whose sweat was well neere as blood, & in this manner he proceeded untill he saw they had sweat sufficiently, causing them to use in the meane time an excellent fine diet of wholesome meats: sundry desperate diseases were cured by him, yea they seemed more young and lustie that used this order then they were before; but no intreatie or promise of reward, nor all the meanes that could be used to him, would make him reveale this secret to any, or tell what herbe it was whose juice he used.

## CHAP. LXIIII.

*Herba vita amant mortem in morbis prænuntians.* The Indian Fortune teller of life and death.

A Certaine Indian of chiefe account comming into the count *de Nieva* his house that was in *Peru* upon some occasion of businesse, saw a woman servant of the house very sad and sorrowfull, for that her husband lay then very sicke of a grievous disease, he asked her if shee would faine know whether her husband should thereof live or dye, she saying yea, he sent her a branch of an herbe which he willed to be put into his left hand, and there to hold it fast, which would make him seeme pleasant and merry if he were to live, but sad and sorrow full if he should dye, which she so using it and finding her husband sodainly to become sicke that she thought he would presently have departed this world, she pulled the herbe out of his hand and threw it away, but within a short time after this her husband dyed: but *Monardus* saith he doubting of the truth thereof enquired of divers and it was affirmed unto him by a noble man that had long lived in *Peru* that it was true, and that it is usuall with the Indians to doe so in diseases, which is a matter of great admiration and wonder.

## CHAP. LXV.

### 1. *Herba Viva.* The Herbe of life or love.

THere are two sorts of this kinde of plant that are to be distinguished in sunder, and not to be accounted all one as divers have thought that are knowne to us of late (and yet I thinke verily there be some others of the same nature, not sufficiently yet made knowne to us, which I gather out of the writings and relations of divers. The one is an herbie plant without any prickes or thornes thereon, for any thing that I can learne thereof, and is this I am now about to shew you: The other is both a shrubbe, or as some say a tree, and thorny also which shall follow. *Garcias ab Orta* first maketh mention thereof to grow in divers places of the East Indies but giveth it no name. *Acosta* saith it is called by the Christians there generally *Herba viva*, and of the Indians *Herba amoris*, of the Arabians and Turkes *Suluc* and *Suluque*: The leaves are compared by them unto the leaves of *Pollipody*, but *Acosta* rather compareth them to the leaves of *Orobus*, foure or five, or divers rising from the roote, each upon its footstalke, being winged with many smaller ones then those of *Orobus*, set on both sides of the stalkes, which are about two inches long a peece, of a pleasant greene colour very beautifull; among which leaves rise up divers slender bare naked stalkes, each of them bearing one flower at the toppe in forme somewhat like unto a Pinke, but of a yellow colour without any sent at all. The admirable propertie hereof is, that if any shall touch it with their hand, and some say that if any man doe but breath upon it, it will presently draw it selfe together, and if one would take it into their hand it will close together as if it were dead. But that which is more admirable is, that if they shall withdraw their hand it will quickly after as it were revive againe and spread it selfe as it was before it was touched, and this it will doe many times in a day if it be touched and let alone againe without touching. Other properties it is sayd to have, as to restore Virgins that have beene defloured, if ye will beleeve it, to procure love betweene man and woman, and as *Acosta* saith he was informed by an Indian Phisition of good credit, that he would cause any woman to be at his will and pleasure, so that he would but declare her name, and use it (or rather abuse it) as he would appoint him, but the fact being unlawfull, he refused the condition.

### 2. *Frutex sensibilis Herba Mimosa dicta.* The Mimicke herbe called the sensitive thorny shrubbe.

This other Mimick, Mocking or Sensitive plant groweth to be a wooddy Shrubbe, yea some say to be a tree, having divers sprigs rising from the root, and branching forth sundry leaves set here and there, with short thornes or prickles, leaning as *Acosta* unto other trees or walls, but *Clusius* saith it spreadeth on the ground taking roote at the joynts, and sundry wings of fresh greene leaves thereon, which upon the touch of any man, or his breathing onely, and not of any thing else would shrinke and seeme as withered; but neither flower nor fruit hath *Acosta* mentioned, but I am enformed from Mounsieur *Iohn de Laet* out of a Spanish relation thereof in a booke printed at *Mexico*, that it beareth flowers and fruit somewhat like unto the Chesnut, many of them hanging downe together in a cluster, being greene at the first and afterwards red, these be others relations: but let mee shew you what I have seene of the living plant as it grew in a pot at *Chelsey* in Sir *Iohn Davers* Garden, where divers seeds being sowne therein about the middle of *May*, 1638. and 1639. some of them sprang up to be neare halfe a foot high, yet others were inferiour, the tallest shot two or three stalkes from the root, somewhat hard and wooddy, with divers joynts on each side, and severall branches thereat, as also a small short thorne at each

1. *Herba Viva.* The herbe of Life or Love.

2. *Frutex sensibilis Herba Mimosa dicta.* The thorny sensitive Shrub or Plant.

joynt, which branches had ſeverall paires of winged leaves ſet oppoſite each unto other, containing ſome eight ſome ten ſmall leaves on a ſide without any ocde one at the end, ſet very cloſe together, being narrow, ſmooth, and of a full but freſh greene colour, not fully round pointed nor dented, foulding themſelves upward cloſe to the middle ribbe, upon any touch thereof, this in the elder growne plant, but in that which was young the whole ſtalke with leaves would fall downe and ſhrinke up the leaves: this I proved in thoſe two ſeverall yeares before recited: the former yeares plants as they grew in the pot, I cauſed a cunning hand to draw to the life, which I here exhibite unto you with the other, that you may ſee the difference betweene it and others formerly ſet forth from the ſight of a dryed plant. If this could have beene preſerved in our Winters, our Sommers would have declared a more ample and full demonſtration thereof. This is ſaid to be not ſo quicke in apprehenſion as the former. It is ſaid alſo that the ſtalkes have the ſmell and taſt of *Licoris*, and are uſed by the natives uſually to helpe the cough, ſhortneſſe of breath, hoarſeneſſe of the throat and voice, to cauſe flegme eaſily to be expectorate, as alſo to eaſe the paines of the ſtone in the Kidneyes, and healeth up freſh wounds. That Spaniſh Author before recited relateth alſo that it procureth ſleepe being applyed to the head, but ſooner with the *Americanes* then the *Spaniards*: ſaid alſo by them to procure love, but could not ſhew how or by what way; it helpeth the Flux or Laske of the belly by that aſtringent and glutinous qualitie therein perceived by the taſte; as alſo *tertian* Agues, and the inflammations and redneſſe of the eyes. The ſaid author ſaith that he underſtood, yet hee knew not how truely that in the *Philippinas* they have ſuch another plant yet differing in ſome particulars, for it is ſaid theirs ſhooteth forth ten or a dozen ſtraight twigs from a root, each of the bigneſſe of an Hens quill, one whereof had a dozen leaves on them in foure rowes ſet at diſtances, ſix inches betweene, being like unto Reddiſh leaves: the flowers were blew like unto a birds tongue before they were open, and divided it ſelfe afterwards into three leaves. This upon touch or breathing thereon would not fall downe as in the former and riſe againe, but ſaid to fall away, that is, the lower leaves and ſo likewiſe the upper leaves if they were touched againe, but the ſtalke alſo would breake off and fall downe upon the touch or breathing, and if they ſhould be broken by any ones hand, the place would ſeeme as black as if it were burne: but that it would not doe ſo if it were toucht with a ſticke or wand. The *Herba Mimoſa* ſeemeth likely to be the *Æſchinomenes* of *Apollidorus*, whereof *Pliny*, *lib.* 24. *c.* 17. maketh mention. As alſo that tree that *Theophraſtus* ſaith, *lib.* 4. *cap.* 5. grew about *Memphis* in *Egypt* which differed not from other trees, either in forme leaves or branches, but in the event for the outward face thereof was thorny, and the leaves like Ferne (as *Gaza* tranſlateth it) but *Pliny* much better, like feathers, which being touched ſhranke as withered and dry, and by and by after revived againe. The Earle of *Cumberland* in Queene *Elizabeths* dayes brought from the ſacke of *Portricco* ſome of theſe plants, but lived not long in the ayre of *England*; ſome of the dried and dead ones being afterwards ſent to *Cluſius* by *Iaques Garret*, whoſe figure is that he exhibited in his *Chriſtophorus Acoſta*.

## CHAP. LXVI.

*Stirpanimans ſeu Frutex impatiens.* The ſhrinking ſhrubbe.

SOmewhat like unto thoſe before remembred is this ſhrubbe, which our Engliſh which went with Sir *Iames Lancaſter* found by chance travailing neare the Sea ſhore, on the Eaſt ſide of the Ile of *Nicubar*, as alſo on *Sombrero*, an Iland which is neare *Nicubar* & *Sumatra*, the younger ſized, being like ſmall buſhes, halfe a yard or two foote high, at the toppes of whom grew foure or five branches full of leaves ſomewhat round like unto Mirtle leaves, as greene as Sorrell and full of ſap or juice; which buſhes being ſtrucke by ones foot or otherwiſe as they paſſed by, were obſerved to ſhrink downe as low as the branches would let them, and riſe againe by and by after to the former height; the reaſon hereof was, that every plant grew out of the mouth or belly of a long living worme within the earth, which drew downe the plant being ſtrucken; but in the elder or greater growne plants the worme was conſumed, and the rootes of theſe buſhes being plucked up after they had remained a day two or three above the ground, became as hard as Corall: the reſt of the buſhes remayning as wooddy as other ſhrubbes. This threefold change or alteration in nature, firſt from a living worme to a vigetative plant, and then to a ſtony ſubſtance, maketh it more admirable above any.

## CHAP. LXVII.

*Planta animal ſeu Boramez Agnus Scythicus.* The *Scythian* Lambe.

THis ſtrange living plant as it is reported by divers good authors is, called by the Natives *Boramez quaſi agnellus*, by others either *Planta Ruthenica agno ſimilis*, or *Agnus Scythicus*, or by ſome *Planta animal*; it groweth among the *Tartares* about *Samarcanda* and the parts thereabouts, riſing from a ſeede ſomewhat bigger and rounder then a Melon ſeede, with a ſtalke about five palmes high, without any leafe thereon, but onely bearing a certaine fruit on the toppe, in forme reſembling a ſmall lambe, whoſe coate or rinde is woolly like unto a Lambes skinne, the pulpe or meate underneath which is like the fleſh of a Creviſe or Lobſter, having as it is ſayd blood alſo in it; it hath the forme of an head, hanging downe, and feeding on the graſſe round about it, untill it hath conſumed it and then dyeth, or elſe will periſh if the graſſe round about it bee cut away of purpoſe: it hath foure legges alſo hanging downe: the Wolves much affect to feede on them.

CHAP.

## CHAP. LXVIII.

*Manobi forte Brasilianorum.* Indian earth nuts, or Pease.

THere is growing in sundry places in *Brassil* and in *America* also, neare the River *Maranon* a certaine fruit or Pease breeding under the ground like as puffes doe, without either leafe or roote as it is sayd, but they are no bigger then great Pease, and inclosed in a small grayish thicke and short cod, very like a small Pescod, with one or two Pease therein, of a pale reddish colour, on the outside and white within, tasting like unto an Almond, which will rattle being shaked in the skinne, growing many together and tyed by small strings. The fruits are eaten as junkets with great delight, for their pleasant tastes sake eyther fresh or dryed, but a little tosted make them rellish much better, and are served to the table of the better sort as an after course, and doe dry and strengthen the stomacke very much, but taken too liberally breed head ach and heavinesse.

## CHAP. LXIX.

*Radix Sanctæ Helenæ.* Saint *Helens* beads, or Indian round sweet Cyperus.

NEare the Port of Saint *Hellen* which is in *Florida*, grew certaine rootes very long and full of knots, or round joynts as great as ones thumbe, blacke without and white within, tasting somewhat aromaticall like *Galanga*, which when they are dry are as hard as an hornē, the leaves are large and very greene, growing on stalkes that spread on the ground: it groweth in moist grounds, and is drying in the beginning of the second degree, and heating in the end of the same, the pouther of them taken in wine is ated against the paines of the stomacke and bowels, easing the collicke and stone in the Kidneyes, and provoking urine. The Indians use to sprinkle the pouther of the rootes all over their bodies, being ready to goe into the Baths, because as they say, it bindeth the skinne and strengtheth the members of the body by its sweet sent. They use there to disjoynt these round knots of the rootes, which being drilled and strung serve them in stead of Beads to tell God how many prayers they will give him at a time. *Clusius* thinketh these roots may not unfitly bee referred to some kind of *Cyperus*, but I thinke the large leaves contradict it.

*Radix Sanctæ Helenæ.*
Saint *Helens* Beads, or Indian round sweet Cyperus.

## CHAP. LXX.

*Radix Quimbaya.* *Carthagenas* purging roots.

PEtrus Cieca maketh mention of these roots in the first part of his *Peruvian* history that they arē slender, of about a fingers thicknesse, growing among the trees in *Quimbaya*, a Province in *Peru* whose cheife city is *Carthage*: if some of these roots be taken and steeped in a good quantitie of water all night, they will drinke up most of the water, but yet three ounces thereof remaining being drunke doe purge the body so gently and without trouble or perturbation, as if it had beene purged with Rubarbe, this hath beene often tryed. *Clusius* thinketh that these rootes were the same or very like unto such as was sent him by a friend by the name of *Bexugo vel Peru*, which he tooke to be no other then the branches of *Atragene* or *Viorna* of that Countrey, they were so like.

## CHAP. LXXI.

*Rhabarbarum Americanum.* Rubarbe of *America* or West Indie Rubarbe.

MOnardus saith, that among other things were sent him out of the maine of thē West Indies he had a peece of a roote which they called there by the name of Rubarbe, and was very like the East Indian kind, for as hee saith it was round, with a brownish coate and reddish core or inside, which being broken, had some whiteneſse mixed among it, and coloured the spittle yellow like Saffron, being bitter withall, but what leaves it bore was not signified. This is not the white Rubarbe of *America*, for that as is sayd in its place is the *Mechoacan*.

## CHAP. LXXII.

*Carlo Sancto.* The Indian Hoppe-like purger.

OVt of the Province of *Mexico* commeth this root which they there call *Carlo Sancto*, for what cause is not well knowne, it groweth after the manner of Hoppes, climing on poles or other high things, or else it will lye on the ground: the leaves are like unto Hoppe leaves, of a very sad greene colour, and of a strong heady sent: it is not knowne whether it beare eyther flower or fruite: the roote is great at the head, having sundry smaller sprayes issuing from it, each of the bignesse of ones greater finger and white, the barke or rinde whereof is easily seperated from the rest, and is of most use, smelling somewhat sweet, and tasting bitter and somewhat sharpe withall: the pith of the roote consisteth as it were of many small and very thinne filmes which may easily be sepearated one from another: it is hot and dry in the beginning of the second degree. The barke of the roote being a little chewed in the mouth draweth downe from the head much flegme, whereby rheumes catarrhes and destillations therefrom are voyded, and the parts much eased of paines and other griefes, in some also it causeth a vomit, avoyding thereby much choller and flegme from the stomacke, that oppressed it before and strengthned it afterwards, the decoction thereof worketh better thereon; if a purgation fitting the person be taken before this evacuation upwards, it will doe the more good: the barke being chewed helpeth loose gummes, putrid and rugged teeth, and maketh a sweete breath, but it were good to wash the mouth with a little wine afterwards to take away the bitternesse: the pouther thereof taken in a little white wine, or the decoction thereof with Maiden haire and a little Cinamon easeth women of the obstructions of the mother, the staying of their courses, and consumeth winde in their bodies being formerly purged and prepared, and using *Liquidambar* & *Ung Dealthæa* of equall parts mixed together, to annoint the lower parts of the belly all the while: the same also helpeth the Simptomes of the heart, as swounings and other the passions thereof, especially rising from the defects of the mother. This decoction likewise is very beneficiall for them that are so troubled, that is to take two drams of the barke, and boile it in three pints of faire water, putting in at the end thereof foure drammes of the barke of Pomcitrons and two drammes of Cinamon, which afterwards being strained, six ounces of this decoction is to be taken with a little Sugar every morning, the body being purged before hand. This pouther and decoction is commended likewise against the French disease, the Epilepsie or falling sicknesse in the younger sort: the pouther thereof hath beene often found to cause women to have a speedy delivery, and to take away the passion and faintings in their tedious travailes, being taken either in wine or in some Orenge flower water, the continuall use thereof hath beene tryed to amend a cold and weake stomake, and to helpe such as could digest no meate: the like use hath given remedy and perfect cure to those that have beene bursten, so that they have not used any Trusse to themselves being perfecty helped thereby.

*Carlo Sancto.* The Indian Hoppe-like purger.

## CHAP. LXXIII.

*Fabæ sive Phaseoli purgantes.* Purging Beanes.

MOnardus speaketh of certaine purging Beanes that grow about *Cartagena* and *Nombre de Dios* very like unto our ordinary Beanes but lesser, with a thinne outer skinne, dividing it in the middle which was to be cast away, least it might procure too violent evacuation both upward and downeward, even to the hazard of life. With the Indians this is a famous and familiar medecine, purging without trouble flegme, and choller, and grosse humors, and that very gently, the quantity to be taken is from foure of them or more according to every ones abilitie, but you must regard that every one of them bee rosted well before they be used, but *Clusius* saith he could never see such beanes as are here described, but hath had a certaine kind of *Phaseoli* Kidney beanes sent him under the name of *Fabæ purgatrices*, whose figure is here exhibited, being round and flat on both sides, about a fingers thicknesse and two in breadth or more, yet a little hollow on that side where it grew to the huske: the outer huske is hard, and in a manner woody, smooth, and of a darke red colour, being white, and of a firme substance within parting

*Fabæ sive Phaseoli purgantes.* Purging Beanes.

in

into two as most other pulses do, of the like taste also at the first, but quickly hot and sharpe upon the tongue, from whence commeth as it is likly the purging quality: because in some sort these resemble the forme of a heart, therefore some called them *Cor Divi Thomæ*, Saint *Thomas* hearts, and besides because they grow in Saint *Thomas* Island. *Clusius* thinketh that this is the Beane of the *Phasiolus Brasilinus*, whose pods I have shewed you in page 1057. *Monardus* also speaketh of purging nuts, which he calleth *Avellanæ purgatrices*, which grew in *Santo Domingo* that were very like unto teasell, Hasell nuts, but three square and browne on the outside, with a tough thin shell the kernell being white and sweete withall, whereby many were deceived: for they purge very violently both upwards and downewards choller and flegme, even almost to the danger of life, which by roasting of them before the taking is avoyded: they helpe the Chollicke, and expell winde, and are often put into glisters for that purpose; but I have knowne a glister given in this manner to good purpose: a glister being ready to be given with bladder, the small end of a Tobacco pipe was put into the bladder and tyed (but so that it might bee drawne closer after the pipe is pulled out) that had Tobacco in the Bole, which onely blowing the smoake thereof into the bladder and so given hath given present ease.

## CHAP. LXXIIII.

### *Faalim Theveti. Mombazas* Antidote or Counterpoyson.

ANdræas *Thevet* mentioneth this herbe in his *Cosmography* to grow in the Island of *Mombaza*, having many long leaves like unto *Elecampane*, which Island as it aboundeth with many singular good herbes, both for meate and medecine, so it doth also with venomous Serpents: for whose remedy it is also especially provided of other powerfull herbes, among whom this one is accounted a principall: the experience whereof saith hee I have seene upon divers people bitten by a most virulent Serpent, there called *Alefab*, partly living in the waters and partly upon land, whose venome was present death, if the patient were not suddenly succored herewith.

*Maalim Theveti. Mombazas* Antidote or Counterpoyson.

## CHAP. LXXV.

### *Herba Malucana.* The poore mans Chirurgery.

THis herbe riseth usually to be two or three cubits high, but in more fertile places to be above five cubits, of a fresh greene colour, the stalke is slender weake and hollow, leaning unto something to uphold it, or else it will lye on the ground, where it will take roote againe, it spreadeth into sundry branches, having tender soft leaves thereon like in forme and begnesse unto Elder leaves, but dented about the edges, the flowers are like Camomill but all yellow and greater; it is greene all the yeare through; those of *Canaria* call it *Brungara aradua*, and the vulgar sort, Poore mens remedy and Chirurgions baine, because the common people of India doe generally plant it being naturally of *Maluca*, and use it for all hurts, eyther alone or mixed with other things that serve for the purpose: the manner whereof is thus, They boyle the bruised leaves in oyle, which after it is well boyled and strained they make an ointment thereof with a little yellow Wax; and herewith they dresse their sores, be they old or young, bloddy, putrid, malignant or fistulous, and especially is good in the foule sores of the legges, Another way they have to use it by taking the middle or inner rinde, the outermost being taken away, which is as easily done as in Hempe, and annointing

it with the oyle of the Indian Nut, they rowle it in the leaves thereof, and roſt it under the hot embers, which being growne ſoft, they beate it and then apply it to all ſuch wounds and ſores aforeſaid, which are perfectly cured within a few dayes, without inflammations or Impoſtumes, to the wonder of all that knew it not before: it likewiſe eaſeth all paines, and ſtayeth all fluxes of blood, and is a ſingular helpe to the joynts that are pricked or wounded, and briefly ſerveth the people that uſe no other remedy to helpe themſelves in any caſe of neceſſity, without the uſe of a Chirurgion, and truſt thereto as unto an undoubted remedy; the oyntment is carryed into ſundry other Countryes alſo. Another herbe called *Centella* groweth in the Weſt Indies, mentioned by *Monardus* out of *Petrus de Oſma* his Letter to him, who without any deſcription thereof, ſaith that the Indians doe familiarly uſe it, and the *Spaniards* from them, being bruiſed and laid to any tumour in the legges or thighes, comming from a cold cauſe, would cure them by raiſing bliſters that the humours might be let out, and the ſwelling aſſwaged. Another herbe alſo *Monardus* there remembreth from him likewiſe, that would ſtanch the blood of any wound ſuddenly, ſeene, and tryed by certaine captive Indians, that through hunger cut off the calves of their owne legges and did eate them, and preſently applyed the leaves to them, which ſtanched the blood to the great admiration of all that ſaw it. The ſame *de Oſma* ſaith there, he uſed a kinde of herbe growing like graſſe, which of himſelfe tooke the name, which being chewed would draw downe much flegme, and therefore good for rheumes in the head, and defluxions into the throate, and to make lotions to helpe thoſe diſeaſes thereof.

*Canella.*

*Herbe folia ſanguinem ſiſtens. Gramen quod ad pituitam.*

## CHAP. LXXVI.

*Herba Ioannis Infantis.* *Iohn* the Infants herbe.

THis is a ſmall herbe growing in the Weſt Indies having leaves like unto Sorrell, but ſomewhat rough and hairy, and tooke the name from one *Iuan Infanta* an Indian, the ſonne of a *Spaniard*, who uſed it to cure wounds, and to ſtanch their bleedings, helping all hurts, prickes, and wounds in the ſinews, or in any other part of the body, digeſting, cleanſing, and healing them by laying ſome of the greene herbe bruiſed thereunto: or elſe the pouther of the dryed herbe ſtrowed thereon, which is thought to be better then the greene herbe.

## CHAP. LXXVII.

*Lactuca ſylveſtris pumila.* A Lettice for the tooth ache.

ANother herbe was ſent unto *Monardus* out of *Peru*, that was like unto Lettice leaves, but of a darke greene colour, and very bitter in taſte, the decoction whereof kept a good while in the mouth, on that ſide that the tooth doth ake, will eaſe and take away the paine: the juyce of the greene leaves put into an hollow tooth will doe the ſame.

## CHAP. LXXVIII.

*Mungo.* Indian Coriander like ſeed for an Ague.

THe Indians of the Eaſt have a ſmall round ſeed very like unto Coriander ſeed, which is greene before, but blacke when it is ripe, being fodder given to horſes, and men doe alſo eate of them; they of *Guzarate* and *Decan*, uſe the decoction thereof againſt agues, and giving, the ſeed alſo being husked, and boyled like Rice, unto their aguiſh patients cauſing them to abſtaine from either meate, of bread of Wheate, for many dayes together: It is held that *Avicen* mentioneth this in the 481. Chapter of his ſecond Booke, by the name of *Meſſe*, *Bellunenſis* his interpreter hath it *Mens*, but *Garcias* ſaith it ſhould be *Mex*, and ſo in another place he nameth it.

*Mungo ſimilis fructus.* Indian Coriander like ſeed.

*Mungo ſimilis.*

There hath beene ſent alſo another ſmall creſted graine or ſeed, of the bigneſſe of Pepper cornes, ſo like unto Coriander ſeed, that at the firſt ſight, one might be ſoone miſtaken, but that it is greater and blacke, this might be thought to be the former *Mungo*, but that this is hot, and the *Mungo* is cold, as it is thought fit for ſuch patients.

## CHAP. LXXIX.

*Arbor Bon cum fructu ſuo Buna.* The Turkes berry drinke.

ALpinus in his Booke of *Egiptian* plants, giveth us the deſcription of this tree, which as hee ſaith, hee ſaw in the garden of a certaine Captaine of the *Ianiſſaries*, which was brought out of *Arabia fœlix*, and there planted as a rarity, never ſeene growing in thoſe places before. The tree ſaith *Alpinus*, is ſomewhat like unto the *Evonymus* Pricketimber tree, whoſe leaves were thicker, harder, and greener, and alwayes abiding greene on the tree; the fruite is called *Buna*, and is ſomewhat bigger then

then an Hazell Nut and longer, round also, and pointed at the one end, furrowed also on both sides, yet on one side more conspicuous then the other, that it might be parted into two, in each side whereof lyeth a small long white kernell, flat on that side they joyne together, covered with a yellowish skinne, of an acide taste, and somewhat bitter withall and contained in a thinne shell, of a darkish ash-colour: with these berries generally in *Arabia* and *Egipt*, and in other places of the *Turkes* Dominions, they make a decoction or drinke, which is in the stead of Wine to them, and generally sold in all their tappe houses, called by the name of *Caova*; *Paludanus* saith *Choava*, and *Rauwolfius Chaube*. This drinke hath many good Physicall properties therein: for it strengtheneth a weake stomacke, helping digestion, and the tumours and obstructions of the liver and spleene, being drunke fasting for some time together. The *Egiptian*, and *Arabian* women use it familiarly while their courses hold, to cause them to passe away with the more ease, as also to cause those to flow that are stayed, their bodies being prepared and purged aforehand.

*Arbor Bon cum fructu suo Buna.*
Turkes berry drinke.

## CHAP. LXXX.

### *Curcus.* White Nuts.

THere growēth saith *Garcias* in divers places of *Malavar*, a certaine Plant which is sowen and hath the fruite thereof hanging downe from the branches that are like unto Hazell Nuts, but not so round, and white of colour, whose kernell is sweet somewhat like unto Mushromes, or *Spanish* puffes, when they are boyled and dressed: they call it *Quiviquilenga* in some places (which signifyeth saith *Garcias* a small *Inhame*, but *Clusius* saith he knoweth it not, except it be the *Trasi dolce*, or *Juncia avellanada*) and in *Malavar Curcas*, and in *Cambaya Carpata*: these saith he, are not put to any use in physicke that he knew: he doth conjecture that *Serapio* meaneth this fruite by the name of *Habaconlcoul*, which saith he, breedeth abundance of sperme, but bringeth the passion of the chollicke therewith.

## CHAP. LXXXI.

### *Caceras Indorum.* Indian Trasi rootes,

THis roote groweth within the ground like as Trasis doe, shooting forth stalkes in the dry time of the yeare, having leaves like the water Flagge, or Corne Flagge, one foulded within another: these rootes being dryed taste like unto Chesnuts: but while they be greene or before they be dryed, they are unpleasant. *Clusius* thinketh that these rootes be the *Malinathalla* of *Theophrastus*, *lib.* 4. *c.* 10. or the *Anthalium* of *Pliny*. About the River *Maragnon* in *Peru*, grow certaine fruits under the ground like *Spanish* balles, of the length and bignesse of halfe ones fingers, round and somewhat writhed, of a brownish colour, having within it a small nut like an Allmond, which will rattle being shaked when it is dry, browne without and white within, parting in two parts as an Allmond, of as good a taste as a Filberd, both raw and roasted, but procuring headache if too liberally eaten: they dry and strengthen the stomacke, and are esteemed as junkets with the Indians and *Spaniards*.

*Fructus sub terra nascentes. Quere an Manobi supra.*

CHAP.

## CHAP. LXXXII.

*Bangue.* The Indian dreamer.

THis herbe groweth up with hard stiffe square stalkes like unto Hempē, yēt tough and not ēasie to breake nor so hollow as Hempe, whose barke may be drawne into threds as well as Hempe (yet *Garcias* saith the stalke is wooddy, with but a little barke) of a pale greene colour: the leaves are like unto those of Hemp, dented about the edges, greene on the upper side, and gray or hoary underneath, of a dry insipide taste: the seed is like unto Hemp seed, but lesse and not so white. The Indians of the East Countries use both leaves juyce and seed thereof, for many purposes both good and bad to stirre up an appetite to meate, and the validity of venerious actions, whereunto they are mighty prone and proclive, and wherein is their chiefe felicity, eating the leaves or seed alone, or with some Sugar, divers also doe diversly compound or mixe it, some putting thereto in pouther *Faufel* or Nutmegges, or Cloves, or choyse Camfire or Muske, or Ambar, according to every ones fancy and ability, or as they would be intoxicated, for it will drive them into sleepe, and then grow great dreamers, according to their humours and dispositions, but if they take it with *Opium*, as the great men and Souldiours oftentimes doe it, will cause deepē sleepes to make them the more able to undergoe their sore labours, travaile, and watchings in the warre, and to forget them also. But the women oftentimes abuse their husbands hereby in giving it them to fulfill their lust before their faces. Although this plant be in face like unto Hempe, yet the qualites are quite contrary.

*Bangue.* The Indian dreamer.

## CHAP. LXXXIII.

*Hiucca sive Mandiocae ex qua Cazavi fit.* The true Indian *Hiucca* whereof the Indians bread *Cazavi* is made.

THe plant hereof groweth like a small shrub or bush of Elder, and is accounted to be of two differing sorts of leaves, and riseth to be sixe or seven foote high, with sundry wooddy stalkes, bearing many faire broad leaves thereon, divided into sundry parts, like unto *Helleborastor*, or the fingers of ones hand, seven or eight together, upon a long footestalke, each part of them being halfe a foote long, and three inches broad, but not endented about the edges, abiding alwayes greene: the one sort of leaves are somewhat broad towards the points, the other narrower, it hath saith my friend that gave me the intelligence, a small spotted flower, but what fruite followed, hath not yet beene signified by any: the roote groweth quickely great, for it is usually planted every yeare, or every other yeare, and becommeth as great and long as a good great Carrot roote, browne on the outside, and very white within, the manner to propagate it is, to cut off a stalke about a foote long, and put it more then halfe way into the ground, where it will quickely take roote, and within a yeare or little more be fit to take up and use againe. Of this roote did the *Americanes*, notwithstanding in many places they had *Maix*, which is Indian Wheate, both in the Isles and in the Continent, for many hundreds of yeares make their bread whereon they lived in this manner: Having pared away the rinde, they scraped or broke small the roote, which is white, sappy, and full of substance, from whence they pressed out the juyce which they kept by it selfe, having an evill smell, whereof whosoever tasted, either man or beast, dyed without remedy, and that quickely, but if they boyled it to the halfe, it would become a good wholesome drinke although like small Ale, and if set in the Sunne it would be as good vinegar as might be of Wine, and if it were boyled thicke, it would be sweete as hony, and serve for that purpose: the masse from whence the juyce was pressed, they did put into a panne and set it over the fire to make it grow thicke, and being dry, they made it into pouther, and putting water thereto they formed it into small cakes, and dryed them in the Sun, which they kept for their use, and would abide good for a long time, twenty yeares without corrupting, giving good nourishment to the body, although it would exasperate the jawes and throate in eating thereof, for which purpose they had need of water, or other liquour, to moisten it often, or else it would be hard to swallow, being somewhat harsh and sharpe in the throate. This ordering of the roote to make poyson wholsome, is no lesse admirable then

that

*Hiuccæ sive Mandiocæ genuinæ Mexicanæ species duæ foliis Cannabinis.* Two sorts of the true West Indian Hempe leafed *Hiucca.*

*Hetich Americanum.* Mallow leafed Potatoes.

that the juyce of this roote groweth on the Vpland in the Continent, is not any whit hurtfull, as it is said, although it be hurtfull in the Islands: & this bread was used by all the people of *America*, from *Florida* to *Peru*, and about to the Straights of *Magellane*, above a thousand miles, yet had they *Maiz* also, that is, Indian or Turky Wheate, in most of those places. The Names hereof are very various, according to the Country, for it is called *Manihot* by some, *Hiurca*, *Hiucca*, or *Iucca*, according to others, and *Cazavi*, as they call the bread which the *Spaniards* doe write *Cacavi*, that is *Casavi*, which is the most generall name through all places. We have not heard that the Indians used either herbe or roote to any Physicall remedy.

Like hereunto is that which is called *Hetich* by the Indians, whose leaves are round like Mallowes, and the roote like unto great long Turneps, being of two sorts, the one being yellowish the other white, when they are boyled or baked into bread, and is planted from peeces cut off from the roote. Some would referre this to the *Vingum* of *Theophrastus*, which *Pliny* calleth *Oetum*. *Hetich Americum.* Mallow leafed Potatoes.

## CHAP. LXXXIV.

*Cevadilla sive Hordeolum causticum Americanum.* The Indian Causticke Barley.

MOnardus saith that among other rare seedes and plants, that were sent him from *Hispaniola*, he had this also, which they there called *Cevadilla*, that is to say *Hordeolum*, Small Barley, from the likenesse of the spiked head of seed unto an eare of Barley but lesser, having the seed enclosed in the like chaffie huskes, but is like unto Linseed, yet greater, whose property is more admirable then ever was heard of in any other herbe or seed, for neither *Sublimatum* nor fire it selfe can effect more in a cautery to be used, therefore it will kill the wormes that breed in foule ulcers, and clenseth those that are foule and stincking, by casting some of the pouther thereinto, yet with discretion, according to the greatnesse and foulenesse of the sore, and using those remedies that are fit for it, but if it chance to worke too eagerly or sharpely they use to dippe tents in Rosewater, or Plantaine water, and put them into the ulcers, it is used in the like manner, for the sores of beastes: this seed is hot in the fourth degree, and beyond it, if there were any further degree to be rekoned,

*Millo* is a graine or kind of Corne like Millet, used both for bread and drinke in the Kingdome of *Sabo* in *Guinea*, remembred in the Sea voyages of *Vanderhague*, in *Clusius* his *Curæ posteriores*.

*Cevadilla sive Hordeolum causticum Americanum.* The Indian causticke tree.

*Millo.*

## CHAP. LXXXV.

*Anana seu Pina.* The West Indian delitious Pines.

THe Pines (so much esteemed for the most excellent and pleasant sweete fruite in all the West Indies) is the fruite of a kinde of Thistle, growing with many long, hard, tough stiffe and narrow leaves, thickest in the middle, and thinne, cut in and dented about the edges, with reddish points, seeming prickely like a Thistle, but are not, from the middle whereof riseth up a round and shorter stalke, then that of the wilde sort set with the like leaves but lesser, and at the toppe one head, of the bignesse of a reasonable Muske-Melon, or Pome Citron, of a yellowish greene before it be ripe, and more yellowish, being through ripe, shewing as it were scaly like an Artichoke at the first view, but more like to a Cone of the Pine tree, which we call a Pine Apple for the forme, yet the outside hath no hardnesse at all therein, but may be pared and cut like unto a mellow Cotone Peach, being so sweete in smell that they may be perceived where they be afarre off, of a farre more pleasant sweete taste and substance then it, tasting like as if Wine, Rosewater, and Sugar, were mixed together, having no seede at all in it, whereby it may be encreased: but as some others say, it hath whitish seed like a Muske-Melon, but lesser and longer; this fruite beareth a bush of leaves at the toppe, and some small heads on small branches underneath it, which being taken from it and planted halfe way deepe in the ground will take roote, and beare fruite the next yeare, which is the onely manner of propagating. In *Brassill* is said that they have sundry sorts hereof, one they call *Iajama*, which is longer and pleasanter then any other, and of a yellowish substance: another they call *Bonjama*, being whiter within, and of a mawmish taste, with the lusciousnesse: a third they called *Iajagna*, white also within, but tasting like sweete Wine with a little tartnesse. The roote is great with many strings thereat, but perisheth with the stalke after the fruite is ripe. It was first brought from *Santa Cruise* in *Brassill* where it is naturall, into both West and East Indies, being not naturall to either of them, but is onely manured there, and now is growne plentifull: they of *Brassill* call it *Nana*, others *Anana*, the *Spaniards* and *Portugalls Pinas*, from the likenesse, and so doe most Countryes, following that name, *Oviedus* in his History calleth it *Iajama*, and *Thevet* in his singularities maketh mention of another fruite very like hereunto but growing upon a tree like the Mulberry, with long broad leaves like Angelica, in an Island of the East India called *Necumere*, which fruite they call *Melenken*, and tasteth as if Sugar and a little Nutmegge were mixed together, which the Natives eate to quench their thirst. The chiefest time of their ripenesse is in the Lent, when they are sweetest. But this *Pina* as I said, surpasseth all other fruites of the West Indies, for pleasantnesse and wholesomenesse, so that many eate them abundantly, and thinke they cannot sufficiently be satisfied with them,

*Anna seu Pina.*
The West Indian delitious Pines.

*Anana sylvestris.*
Wild Indian Pines.

bur

but the surfet of them is dangerous, even as it is usuall of the best fruits: it is not used Physically hitherto that I can learne, but *obsaporis gratiam* wholly spent and eaten: the Phisitions there forbid it their sicke patients, because it is somewhat too hot and might breed inflammations. Some admirable things are reported thereof, one is that if one of these fruits be cut through the middle with a knife and they joyned together againe, the peeces will joyne and sticke so fast together as if it had not beene cut at all: another propertie it hath, that if one cut the fruit with a knife and leave the knife sticking therein untill the next day, so much of the blade thereof as stucke within the fruit will be found wholly consumed and wasted, or as it were eaten away: the knife also that did cut one of them if it be not sodainly wiped but let alone unwiped will seeme as if it had beene eaten in with *Aqua fortis*.

There is another wild kinde of *Pinas* growing naturally both greater higher and more prickly or Thistlelike, having a great tuft of leaves at the bottome of their stalkes or stems next the ground seeming to be Aloe leaves a far off but lesser, and of a pale greene colour set with sharpe prickes, it is encreased by the of-sets, one rising from another: from the maine stem grow sundry branches bearing at their ends, heads of soft tender leaves closed round together, which are nothing but the flowers, and are of a yellowish colour smelling very sweet: out of these heads rise spikes not unlike to those of the Reede but thicker, closer set and farre more beautifull, smelling like the Cedar: from the branches hang downe the fruit called by the *Portugalls*, *Ananas bravas*, that is, wild *Ananas* or *Pinas* which doe somewhat resemble the former or manured kinde, of the bignesse of a Melon, of a beautifull red colour very pleasant to behold which is divided into parts like unto Cipresse nuts when they are dry, and set with bunches or knobs, very neare resembling a Cone or Pine Apple, which are nothing so good although a little pleasant, yet somewhat harsh withall, whereof few doe eate or take pleasure in them, and give as little good nourishment when they are eaten, and is therefore more Phisically used, for six or eight ounces of the juice taken in a morning fasting with some Sugar, is a most present and certaine remedy against the heate or inflammation of the liver or backe, as also against the Vlcers of the Kidneyes, and foule purulentons urines and the excoriations of the yard: all which diseases this cureth upon three times taking.

## CHAP. LXXXVI.

### *Melo carduus Americanus.* The Melon Thistle.

THis admirable plant or fruite hath neither leafe nor stalke, but riseth immediatly out of the ground, from a small whitish rough stringy roote and many small fibres thereat, into the forme of a Muske Melon for the bignesse, but made Cone fashion, that is, broad and flat below, and smaller up to the toppe, having round about it foureteene ribbes set with sharpe crooked prickes ten or twelve together like a starre in six, seven or eight places of every ribbe and furrowed betweene, of a yellowish greene colour: from out of the toppe whereof thrusteth forth sundry silkelike downe or Cottony threds, as the Artichokes and other Thistles doe, within which lye when they are ripe small long slender pointed sheathes or cods, of a perfect crimson colour, resembling the long codded *Capsicum* or *Ginny* Pepper, wherein is contained small round seed like the *Amaranthus*, set with hard yellowish prickes at the head: the rinde hereof is hard and thicke like unto a Melon, which may be pared away like it, under which the pulpe or meate lyeth white in colour, farty in feeling of an unsavory sower taste, waterish and cooling. This plant groweth neate the Sea shores in divers Islands of the West Indies as Saint *Margets*, Saint *Iohns*, and others neare unto *Puerco ricco*. One of the fruits hath beene brought from thence to us that hath weighed seven pounds and twelve ounces. We know of no other use this fruit is put unto, but that in the hot time of the yeare they eate it to quench their thirst and coole the heate of their stomackes.

*Melo carduus Americanus.*
The Melon Thistle.

CHAP.

## CHAP. LXXXVII.

*Carduus Pitahaya Americanorum.* The blood red ball Thistle.

THis Thistly fruit is described by *Oviedus*, growing in the Island of *Hispaniola* which is round, and as bigge as ones fist, and somewhat long, having a shew of scales on the outside: the barke or rinde whereof is thick but may easily be cut or pared, under which the pulpe or meate is like unto a Figge with graines or kernells among it, as it hath, but of a pleasant deepe crimson colour, which coloureth their fingers like Mulberries that eate them, and after two or three houres that they have eaten them their urine will looke whitish, the fruite hath neither leafe nor branch, but riseth up in the middle of many great foure square armes of six foot long a peece channeld in the middle, and both there and at the edges set full of most sharpe but small prickes, three at a place together at certaine distances one from another, the whole plant and fruit is of a pale greene ash colour.

*Carduus Pitahaya Americanorum.*
The blood red ball Thistle.

## CHAP. LXXXVIII.

*Cereus spinosus Americanus.* The Torch Thistle of *America*.

THis small plant seemeth somewhat like the last, but that it riseth up with divers stalkes 19. or 20. cubits high, with some outward ribbes all the length of them, and set at severall spaces with small short thornes standing like small starres, the forme of them very like unto the Melon Thistle, these stalkes have some short branches, and at the toppes flowers like the purple Foxglove, and fruite following of a bright crimson colour like a Figge, but without taste, the stalkes are wooddy of the bignesse of ones wrist of a gristly substance, and of a bitter gummy tast like Aloes.

*Cereus spinosus Americanus.*
The Torch Thistle of *America*.

## CHAP. LXXXIX.

*Planta pinnata arundinacea spinosa.* The winged thorny Reede.

THis Reedelike thorny plant came likewise with the two last recited plants from the West Indies which was like a staffe of a Reede full of pith of eight or ten cubits in length having a threefold waved skinny welt of a fingers breadth set thereon all the length thereof and at the outer ends of the waved welt small starres of sharpe pricks or thornes: more hereof cannot be said for that more was not brought, but that thereby you may behold the admirable workes of God in plants as well as in all his other creatures.

Hereunto is adjoyned another thorny plant brought from these parts, which seemed either the body or the branch of a blacke berry like tree, being a solid firme heavy wood, armed very thicke with great long and strong thornes at certaine tubers or knots, the barke being thicke and blackish.

Observe I pray you that the former of these two descriptions belongeth to the *Cereus spinosus* and that description to be set in the place of it.

*Planta pinnata spinosa & Rubifacie senticosa planta.*
The starre Thistle-like plant of *America*, and a bramble bush-like stalke of *America*.

*Rubufacie senticosa planta.*

## CHAP. XC.

*Cannæ Indicæ portentosæ longitudinis.* Indian Reede staves.

ON the Westerne side of *Sumatra* and in other places also of those Indies grew Canes (for wee know not how else to terme them) or Reedes called by them *Ruttan* of an incredible length, for rising from the ground, they will mount up to the toppe of the highest tree in growth there next unto them, and descending to the ground againe, it will runne thereon on a great way, and sometimes divide it selfe to severall wayes, and afterwards coile it selfe as a Cable is laid on shipbord or else where, to the length of thirtie fathome by computation, and then runne againe over a tree sometimes or else coile it selfe againe as formerly, so that neither beginning or end thereof is found: it hath not beene observed that it hath any leaves on it, but are very plyant and bending as one will while they are fresh and greene, and would serve in stead of ropes: but when they are old and dry, they will serve in stead of walking staves, as they are much used with many of us now a dayes or to any other such purpose, they are no harder or bigger then an ordinary cudgell, yet may one strike fire from them by striking one against another, which nevertheless are porous and hollow as it were in the middle, so that one may blow winde through them at never so great a length, and at a reasonable staffes length almost so strongly, to blow out a candle set at the further end, at the least sensibly to be felt, yet no appearance of holes therein. I take it to be the same that is called *Juncus Indicus porosus* in *Clusius* his *Curæ posteriores*, but why *Juncus* I see no reason.

## CHAP. XCI.

*Canna ingens Mambu vel Bambu dicta.* Huge great treelike Canes or Reeds.

THere hath beene brought us from the East Indies Canes or Reeds of a wondrous bignesse and height, (as may be guessed by the broken peeces) growing in *Malabar* chiefly about the Sea coasts, whereof the inhabitants make posts to build their cottages withall, as also doe cut them at a certaine length like unto a Cowlestaffe to beare burthens, and bend them while they are fresh that they may bee a little crooked and hollowish, to hange a Palankin, that is a couch or litter wherein persons may bee carried in their journying from place to place or otherwise for state or ease, by two or foure Indians: one peece having six joynts was eight foote long, each space betweene the joynts being a foote and foure inches: it was five inches over at the bigger end, and almost as much at the lesser: the circumference or compasse about at the lower end; being sixteene inches and almost as much at the upper: the thicknesse of the wooddy compasse of the Cane was about three inches by measure: and was all overlayd with *Laak*, or *Gum Lacca*, or hard Wax to keep it from the weather, and from cracking in the Sunne, being found in the great Admirall Carrack or shippe of the *Portugalls*, that brought home the Viceroy of the Indies, and was taken by our English 1593. as a Prize; but greater and longer Reedes were brought from those parts by the *Hollanders*, yet not whole but broken, the least whereof was 26. foot long, with 19. joynts therein, being 17. inches about at the lower end and 14. at the upper: a greater was a foote and a halfe longer and three inches more in compasse then the former, the distance betweene the joynts being neare the length of the circumference, or not much differing any where; the thicknesse likewise being three inches or thereabouts as in the former: by these peeces may bee guessed of what huge height these Canes were: at the plants of their Pepper doe they oftentimes fasten downe these Reedes, that the Pepper in the growing may leane thereunto, and be sustained by them, which without some Proppe or stay would lye downe on the ground and become unprofitable. In some places of the Indies say both *Garcias* and *Acosta* these Reed like trees grow so great, that sometimes of them are made small boates, sufficient to hold two naked Indians, which they cleave in the middle and cut off beyond the two joynts, so that an Indian sitting at each end, joyned knee to knee, and a small Oare in each of their hands of halfe a yard long, they will so nimbly force the Boate, yea even against a streame that it is wonderfull to behold, which as *Acosta* saith he saw in the River *Cranganor* where many Crocodils breede which are most fierce and tetrible, and will assaile shippes and other smaller vessells to get some prey out of them: but as it is said will never make assault against any of the boats made of this tree or reede, nor against them in it. Of the roote of this tree being burned is made *Tabaxir*, that is, the *Spodium* of the ancient Authors, as *Avicen* thought, and so *Gerardus Cremonensis* and *Bellunensis* doe alwayes translate the word *Tabaxir*, but *Garcias* sheweth that it is a very false interpretation, there being but one *Spodium* of the Greekes which is our *Lapis tutia* used by them onely in outward medecines, for *Tabaxir* being a Persian word signifieth nothing else but a milky juice or liquor growne thicke, and hereby the *Arabians* do still call that concrete or hardened liquor that groweth betweene the joynts of this Reede or Tree, but the Natives of *Sacar Mambu*, that is Sugar of *Mambu*, but is not found in all places as *Garcias* saith, but in *Bisnagar*, *Batecala*, and some part of *Malabar* chiefly, and is seene to bee of sundry colours, as white like Starch which is the best, yet is it found sometimes of an ash colour or blackish, which yet is not to be misliked, for so it is to be taken out of the Canes, and hath beene in former times esteemed of the value of silver, and yet holdeth a great price even with the Indians, &c. there had neede therefore of great caution of using *Spodium* (as it is taken) in the *Arabians* medecines, which are for the most part all inward which is farre differing from *Tabaxir* as you here see, and of all is taken for the fittest *Antispodium*, and those other of Oxe bones burned and the like to be utterly cast away. The tree hath leaves saith *Garcias* like an Olive but longer: the properties whereof are effectuall eyther in outward or inward heates, hot chollerick Agues and fluxes that come of choller to coole, temper and binde them. And now that I have shewed you all the Physicall herbes let me descend to the trees and prepose them that have delightfull and pleasant fruits, that you may take therein some pleasure to mix with the profitable or admirable that shall follow: and the first that I will propound as *Garcias* saith is the chiefest and choysest fruite in all the Indies.

*Canna ingens Mambu vel Bambu dicta.*
Huge great treelike Canes or Reedes.

CHAP.

## CHAP. XCII.

*Mangas.* The Indian hony Plumme.

THis tree groweth tall like a Peare tree, with somewhat long leaves, more like unto a Peach then a Plumme: the flowers grow from among the leaves, many being set on a long footestalke like the long Birds Cherry, or cluster Cherry, after which follow the fruite, some being as bigge as a small Melon, and weigh neere about two pound, the lesser about the bignesse of a Goose egge, and others betweene these sizes, as the climates and fertility of the soile causeth them, all of them being longer then a Plumme, and with a thinne skinne, greene before they be ripe, but of a yellowish greene and some reddish when they are ripe and shining withall, smelling very well, but tasting much better, and sweeter, so that some are to be eaten when others are reserved to stand, having a long stone in the middle, like unto a long Allmond in the shell, but covered with a whitish downe or freeze, and a white bitter kernell within: Some trees beare twice a yeare, in the Spring and Fall: but generally they are ripe according to the heate, and temperatenesse of the climate even from *April* unto *November* in one place or another, for they are found in many Provinces of India, as *Malabar*, *Balagate*, and *Bengala*, *Guzarate*, *Pegu*, *Malaca*, *Goa*, & *Ormuz*, which are accounted the best, and called generally *Mangas* by the Indians, yet by some *Ambo*, and by the *Turkes* and *Persians Amba*. The fruite is ordered many wayes, as either preserved in Sugar, or pickled up like Ollives before they be through ripe, and are then somewhat harsh and binding: or eaten fresh, being cut into slices and dipped in Wine or without and so eaten. They are cold and moist, and yet the Indian Physitions, as well as the vulgar doe hold them to be hot, saying they breed choller-ricke feavers, inflammations, itches, and scabbes, unto all which diseases they are subject, which eate none of them at all, in respect of the heate of the yeare, when those fruites are chiefely ripe and are eaten. *Acosta* pictureth this tree with flowers, and the fruite much differing from this of *Linschoten*.

There is another kinde found growing in somē places, but much more rarely, whose fruite hath no stone within it, else not differing.

There is likewise a wild kind hereof called *Mangas bravas*, whose tree is lesser then the manured, with shorter and thicker leaves also, and the fruite is of a pale greene colour, having a thicke skinne, and but little pulpe therein, of the biggenesse of a Quince, and with a hard gristly stone within it, yet give they store of milke: they grow generally through all *Malabar*. If any one eate of these fruites although it be but a little, it is so present a poyson that they dye instantly, and herewith the Indians usually destroy one another, some putting oyle thereto, which maketh it the more speedy in operation, but howsoever it is taken it doth so quickely dispatch them out of this life, that there hath not beene hitherto found a remedy against it. Boyes, there doe usually in sport throw these fruites one at another, as in *Spaine* they use to doe with greene Orrenges,

*Mangas.* The Indian Hony Plumme.

*Mangas fructus officulo.*

## CHAP. XCIII.

*Genipat.* The twining *American* Peach.

THis tree is of two sorts, the fruite of the one is edible and greater then the other, which is not to be eaten bearing leaves like the Wallnut tree, and fruite at the end of the branches, being both for colour and bignesse like unto Peaches, one set upon another in a wonderfull manner: that which is not edible hath a certaine cleare blewish juyce therein like unto Indico, wherewith the Savages dye or colour their bodyes when they have any solemne meeting of friends, or goe to the slaughter of their enemies, and they with this ornament thinke themselves as finely decked as we in our bravest silkes.

## CHAP. XCIV.

### *Guanabanus Oviedi.* The Indian Scaly Muske Melon.

THis delicate fruite groweth on a goodly tall tree in sundry places in the West Indies, whose wood is but weake, having large and long leaves, like unto those of the Pomecitron tree, and very greene: the fruite is sometime, as bigge as any Melon, and sometimes of the largenesse of a middle sized Melon, covered with a thinne scaly greenish rinde, somewhat like to a Pine apple for the forme, which may as easily be pared away as a pëare, the meate or pulpe within is very white, sweete, and delicate, and relenting in ones mouth like unto creame: the seedes within are great, like unto Gourdes seed, but somewhat larger and blackish, and are dispersed through the inner pulpe. This fruite is cold and moist, and therefore of especiall use in the heate of the yeare to coole their thirst, and giveth no offence to the stomacke, although one should eate an whole one.

*Guanabanus Oviedi.* The Indian Scaly Muske Melon.

*Anon.* *Oviedus* mentioneth another fruit called *Anon*, which he compareth with the *Guanabanus*, saying that not onely the tree, but the fruite are very like but exceedeth it in goodnesse, being of a firmer substance.

*Thevet* maketh mention of one very like hereunto called by those of the Iland of *Zipanga* where it groweth *Chivey*, which in the *Syriack* tongue signifyeth a Figge. The branch being ripe is yellow, and very pleasant in taste, like unto Manna, melting in ones mouth, containing seede within them like unto those of Cwcombers. The leafe is very round and greene.

## CHAP. XCV.

### *Guanabanus Scaligeri.* The *Ethiopian* sowre Gourde.

THe *Ethiopian* sowre Gourde groweth in *Mozambique*, and other parts of *Ethiopia*, on a faire great tree, having large fresh greene leaves, larger then Bay leaves, & comming neerest to those of the Pomecitron tree, the flowers are of a pale whitish colour, and the fruite as great as a Melon, but longer then it, and ending in a round point, whose rinde is hard and thicke, with sundry ribs thereon, and covered with a greenish freeze or cotton: the pulpe or meate within is whitish while it is fresh, but somewhat reddish being dry, and then is very brittle also, that it may be easily rubbed into pouther, having diverse large seed running through it of the forme of a thicke short kidney or the seedes of *Anagyris*, the great beane Trefoile fastened therein with small fibres to the hollow middle part which pulpe as well dry as greene is of a pleasant sharpe taste, yet more tart or sowre, when it is dry then greene: this is used in the extremities of the hot weather to coole and quench thirst, and is effectuall also in all putride and pestilentiall feavers, the pulpe or juyce thereof taken with Sugar, or the dryed pouther put into some Plantaine water, or the decoction or infusion thereof, both for the aforesaid causes and to stay the spitting of blood, or any other hot fluxe of blood or humours in man or woman; this is very like to be the *Abavo* that *Honorius Bellus* writeth of in his fourth and fifth Epistles to *Clusius* and the *Bahobab* of *Alpinus*.

*Guanabanus Scaligeri.* The Ethiopian sowre Gourde.

*Ficus Nigritarum.* Somewhat like hereunto is that fruite which *Thevet* calleth *Ficus Nigritarum*, the leaves of the tree are larger then any of those former sortes, and hath some divisions therein very like unto Figge leaves: the fruite is sometimes two foote long and thicke, according to the proportion.

*Higuero Oviedi.* Not much unlike also is the *Higuero* of *Oviedus*, which he describeth in his Indian History: The tree (saith he) is as great as a Mulberry, and the fruite sometimes like unto a long Gourde, & sometimes unto a round, of which round sort the Indians make themselves dishes, platters, and sundry other vessels: The timber whereof is strong

and

*Higuero fructus Clusij*
Morrice like Bells.

*Ahovai fructus.*
The poysonous fruite of the stincking tree.

and fit to make stoolēs, chaires, saddlēs, aud the like: the leafe is long and narrow towards the stalke, and broader towards the end, but growing lesse from thence to the point: the meate or pulpe thereof is like unto Gourds, which they often eate in want of better food: This tree groweth in *Hispaniola*, and other the Islands of the West Indies, as well as on the Continent also. *Clusius* setteth forth other certaine fruites tyed unto strings and stones within to sound in dancing with them, which he entituleth *Higuero*, farre differing from this.

*Ahovai Theveti.* The stincking tree with his poysonous fruite.

It groweth as high as a Peare tree, with leaves three or foure inches long, and two broad, yeelding white milke, if any branch bee broken: the wood stincketh most abhominably, bearing a white three square fruite, somewhat like unto the Greeke letter Δ. whose kernell within is most poysonous and deadly, and therefore the Indians doe give great caution to their children that they eate none of them, and themselves abstaine also from using of the wood to burne, but having taken the kernell they putting small stones within the shells, and tying them with strings they serve them for bracers for their legges to dance with, as Moris dancers doe with bells with us.

## CHAP. XCVI.

*Mamay.* The West Indian Peach plumme.

*Caliger* saith this tree is like the Chesnut tree with like leaves yet greater: but *Oviedus* in his history of the West Indies, describeth it to be a faire great tree like unto the Wallnut tree, and with such like leaves, but larger, thicker, and greener on the one side then on the other: the fruite is either perfect round or a little longer then round, as bigge as a good great Quince, some greater, others lesser, covered with a yellow thicke skin or coate, that is somewhat rough and not smooth, the pulpe or meate whereof is very pleasant like unto a Peach, but firmer, and not so sappy as a Plumme, of a yellowish colour, and is of a finger or two in thickenesse, having in the middle two or three kernels, separated by thinne skinnes, that are of a peeled Chesnut colour and taste, but very bitter in the inner kernell.

## CHAP. XCVII.

*Guajava.* The West Indian Bay Plumme.

THis tree (which is very frequent and well knowne through all the West Indies, and which they call *Guayabo*, as they doe the fruite *Guayaba*,) groweth great like unto an Orrenge tree, but thinner of branches, bearing large leaves on them, two alwayes set together, and opposite which are like unto Bay leaves but larger, even foure inches long, and one and a halfe, or two inches broad, gray or of an hoary ash-colour underneath, with great ribs and smaller veines therein, but of a sad greene above, smooth, and without any shew of veines almost, somewhat hard in handling, and both smelling and tasting somewhat like a Bay leafe: the flowers are like those of the Orrenge or Pomecitron tree, smelling sweete like the Iasmine; after which followeth the fruite, as great as a small Apple, and like unto a Plum, that is, somewhat long, greene before it is ripe, and yellowish after (yet *Clusius* saith that he received one from Doctor *Tovar* out of *Spaine*, that was blackish, light and shrunke, which he imputeth to the unripenesse of it) some having a reddish pulpe within, and some a white, very sweete and delicate in taste, divided as it were into foure parts, in each whereof lye many small graines or hard white kernells. The properties of the fruite besides the delicacy to be eaten, hath an astringent power therein to stay laskes, especially if they be eaten while they are greene and not ripe.

*Guajava arboris ramus & fructus.* The West Indian Bay Plum.

## CHAP. XCVIII.

*Ambares.* The hard gristly Plummē of India called *Ambare.*

THe leaves that grow on this great tree, called *Ambare* by all the Nations there abiding, although they seeme somewhat like those of the Wallnut tree for the largenesse, yet are they not of that fashion, for being small at the bottome, and they are broadest at the end, and a little dented in in the middle thereof, elaborate with many veines, and of a pale greene colour: the flowers are small and white, and the fruite that followeth of the bignesse of a Wallnut, with a smoother and paler greene skinne, of a strong heady sent, and sowre harsh taste being unripe, but yellow when it is ripe, and of a more pleasant sent, containing a hard gristly substance within them, with sundry crosse hard nerves or threds running through, yet of so pleasant a tart sowre taste that commendeth it much, and therefore are used by the Natives and strangers also instead of vinegar, or such like sawsē, to rellish their meate, and stirre up an appetite, being eaten with salt and vinegar, while they are fresh or pickled to serve for the yeares following, which endure very well: they use to give the fresh fruite also to those that have hot agues, to coole their blood and humours.

*Ambares.* The hard gristly Plumme of India called *Ambare.*

## CHAP. XCIX.

*Melo Corcopali.* The *American* Quince Melon tree.

*Corcopall*, is a Province of the Indies, wherein as also neere the *Promontori Comari*, groweth a tree like unto the Quince tree, both for forme and leafe, bearing a large fruite as great as a Melon, with ribbes on the outside like thereunto, very sweete and pleasant to be eaten, and physicall also, within which lye three or foure graines or kernells like Grape stones, which are as bitter as Cherry stone kernells: the sicke as well as the sound doe eate of this fruite, having a quality therein to evacuate evill humours.

In the same Province also of *Corcopall* groweth a white Medlar as great as an Apple. *Mespilum album.*

## CHAP. C.

*Darian.* The Melon like bearing Orrenge.

THis Melonlike bearing Orrenge is a fruite called in *Sumatra*, *Darian*, is also somewhat like unto the former *Corcopall*, which is as great as a Citrull Cowcumber, having within it five fruites in shape and biggenesse like Orrenges but longer, and taste like unto fresh sweete butter.

## CHAP. CI.

*Carcapuli.* The Indian yellow Orrenges of *Malavar*.

A*Costa* maketh mention of a great tree in *Malabar* called *Carcapuli* differing from the *Durian*, for the fruite he saith is like an Orrenge, when the outer pill is taken away, which consisteth of sundry lumpes of pulpe, not to be separated as they may be in the Orrenge, whose rinde is thinne, smooth, and shining as gold when it is ripe, of an austere taste, and binding quality, yet pleasant, and are good to stay fluxes of all sorts, and to refresh a dejected appetite, taken with sowre milke or boyled Rice; the Midwives give it women in hard labour, to cause a speedy delivery, as also to expell the afterbirth: the juyce is profitably used to cleare the eyes of mists and rheumes.

*Corcapuli.* The Indian yellow Orrenge of *Malabar*.

CHAP.

## CHAP. CII.

*Mala Indica Lusitanis Ber & Bor Acostæ.* Small Indian Apples.

THe tree that beareth this fruite is great, full of branches and leaves, which are somewhat like Apple-tree leaves, but longer and not so round of a sad green on the upper end, & hoary or woolly on the underside, astringent in taste: the flowers are white, made of fine small leaves without any sent, the fruite is of the bignesse and likenesse of the *Injube* fruite or plant, some greater and lesser as well as pleasanter then others, yet in the ripest (which it is seldome seene, that they come to perfect maturity, neither will they last to be transported into other Countries) they hold a certaine binding property, and are good therefore to binde the loose belly, but are not so good as *Injubes* for the stomacke. In *Canara* and *Decan* they call the tree *Bor* or *Ber*, and in *Malayo Videras*, but the *Portugals Mansanas de la India*, that is *Mala Indica*, whom wee have followed: those that grow in *Malaca* are preferred before those of *Malabar*. In Summer these trees are continually seene loaden with those flies (or winged Antes) that worke gum *Lacca* thereon.

*Mala Indica Lusitanis Ber & Bor Acostæ.*
Small Indian Apples.

## CHAP. CIII.

*Iamboloins.* Indian Ollives.

THis tree is somewhat like the Lentiske tree in the barke thereof, but the leaves are like the Strawberry tree with dented leaves, tasting like the Mirtle leaves when they are greene, the fruite is very like unto ripe Ollives, but of an harsh and binding taste, able to draw ones mouth awry, yet being pickled up like Ollives, they rellish reasonable well and serve to procure and whet the appetite, being eaten with boyled Ryce.

## CHAP. CIV.

*Carambolas.* Furrowed tart Indian Apples.

THe fruite, which they of *Malabar* call *Carambolas*, and *Camarix* or *Carabeli*, by those of *Canara* and *Decan*, and *Bolimba* in *Malayo*, groweth on a tree much like to a Quince tree, whose leaves are longer then Apple tree leaves, of a sad greene colour, and bitterish in taste: the flowers are of a dainty blush colour, but without sent, and of a sower or tart taste like to Sorrell: the fruite is of the bignesse of a good egge, but somewhat long withall, yellow on the outside, hanging by a shore

and ſhort ſtalke, and ſet in the ſmall huske, that formerly held the flower, being pointed at the end, divided as it were into foure parts, with furrowes, which being deepely impreſſed therein, make it the more gracefull, of a pleaſant tart taſte, very pleaſing to the palate and ſtomacke, in the middle whereof are contained ſmall ſeedes. Theſe fruites are much uſed as well to pleaſe and ſtirre up the appetite by reaſon of their pleaſant ſharpeneſſe, as in hot and chollericke agues alſo, either the juyce of them made into a Syrupe, or the whole fruite preſerved in Sugar, or pickled up in brine to ſerve for aftertimes: ſome uſe the juyce thereof with other ocular medicines for to take away the haw, or the pinne and web in the eyes, or any filme beginning to grow over them.

*Carambolas.* Furrowed tart Indian Apples.

## CHAP. CV.

*Iambos.* Blood red, and bluſh Peares of India.

THere is another Indian fruite worthy to be remembred as well for the beauty it beareth in the ſhew thereof, and the ſweete ſent and taſte it carryeth to the other ſenſes, as chiefely for the excellent medicinall properties is now daily found out more and more in it. The tree groweth vaſte, or huge equalling the greateſt Orrenge tree in *Spaine*, largely ſpread with great armes which make a ſpacious ſhaddow: the body and branches are covered with a grayiſh barke, the leaves are very faire, and ſmooth an handfull long or more with a thicke middle ribbe, and other ſmaller veines therein, of a ſad greene on the upperſide, and paler greene underneath, the flowers are of a lively purpliſh red colour, with divers threds in the middle, very pleaſant and ſtanding in a great huske, and taſting like Vine branches: the fruite is of the bigneſſe and faſhion of a King Peare, growing out of that large huske, wherein the flower was formerly ſeated, and are of ſundry kindes, for ſome are of ſo deepe ared colour that they ſeeme allmoſt blacke, ſome have no kernell or ſtone within them, when others have one, which are the beſt: another ſort is of a whitiſh red colour, and ſhining cleare, having a hard ſtone within it like to a Peach ſtone, but ſmooth, and covered with a white rough skinne, which although it muſt give place to the former, yet may well be

*Iambos.* Red and bluſh coloured Peares of India.

accepted

accepted to a dainty palate, the skinne being so tender that as in a Plumme or Cherry, it cannot be pared away, the smell of each resembleth the Rose, and in property is cold and moist. The tree is never without greene and ripe fruite thereon, and blossomes also at all times, which falling abundantly on the ground, make it seeme all red therewith, the ripe fruite by the shaking of the tree are soone made to fall, and gathered from under it, as also easily gathered by hand. The Indians of *Malabar* and *Canara* call it *Iambolin*, the *Portugalls* that dwell there *Iambos*, the *Arabians* and *Persians Tuphe*, and *Tuphat*, the *Turkes Alma*. They there use to eate this fruit before meate most usually, yet they are not refused at other times also: both flowers and fruite are preserved with Sugar, and kept to give to those that have hot agues to coole their stomackes and liver, and to quench thirst.

## CHAP. CVI.

*Iangomas.* Indian Services.

IAngomas are Indian fruites like Services, growing on trees not much unlike our Service treē, both in leaves and flowers, but set with thornes, and are manured or planted in Orchards as well as found wild abroad: the fruite is harsh like an unripe Sloe when it is ripe, and must therefore be rowled betweene the fingers, to make it mellow before it can be eaten, and is generally taken to binde or restraine, whensoever there is cause of such an operation.

## CHAP. CVII.

*Leucoma.* The Indian Chesnut.

THis tree groweth very great, and the wood is strong and firme, having leaves like to the Strawberry tree, the fruite is very like to our Chesnut, as well in colour as bignesse, as also in that white or spot thereon, but it seemed to have the kernell loose within it, for that it giveth a noyse in shaking, the fruit is edible and pleasant, yet a little astringent.

## CHAP. CVIII.

*Charamei.* Purging cornered Hasell nuts.

THere are two kindes of this tree, called *Charamei* by all the Indians generally, but the *Persians* and *Arabians Ambela*, the one is as great as the Medlar tree, with Peare tree pale great leaves, and yellowish fruite, somewhat like to Hasell or Fillberd Nuts, ending in sundry corners, of the taste of sowre Grapes, yet more pleasant, which they pickle up as well being ripe as unripe, and usually eate them with salt. The other kinde is of the same bignesse, but hath lesser leaves then the Apple tree, and a greater fruite, which the Indians use being boyled with Saunders & give the decoction against seavers: the barke of the roote of the former kinde, which groweth by the water sides, is chiefely used (so as it grow farre from the sea) which yeeldeth milke, by taking foure fingers length thereof, which being bruised with a dramme of Mustard seed, they give to those that are pursie and short winded: for it purgeth mightily both upwards and downewards: but if a superpurgation chance thereupon, they give one of the fruits of *Carambolas* to helpe it, or else a draught of the vinegar of *Canara* (which is nothing else but the decoction of Rice set by for a day, two or three, untill it grow sower. The fruite is familiarly eaten through all parts, unripe as well as ripe, and pickled, or eaten with salt and vinegar to procure an appetite, putting it to their meates to give them a rellish by reason of its tartnesse.

*Charamei.* Purging cornered Hasell Nuts.

CHAP.

## CHAP. CIX.

*Iaaca* or *Iaca.* The Diamond fashioned Chesnut Gourd.

THis tree groweth in sundry of the Indian Ilands neare the water sides to be of a vaste bignesse, having leaves of an hand breadth with a thicke hard ribbe all the length thereof, and of a pale greene colour: the fruite is very great (not growing from the younger branches or with the leaves, but out of the body, and elder boughes thereof) long and thick, the least whereof is greater then the greatest Gourd, having a hard thicke rinde of a darke greene colour, set with short Diamond pointed like blackish prickes, which a farre off threaten danger in the handling, but shewing favour in doing no harme, which when they are ripe smel sweet, and grow somewhat soft, that they will yeeld to the pressing of ones hands, and being cut longwise, not athwart, have a thicke yellowish white meate within them, devided into sundry cells or partitions full of long and thicke Chesnut like fruites, greater then any Date, with an ash coloured outside, and white substance within like a Chesnut, which while they are raw taste harsh and breed much winde, but being roasted as Chesnuts use to be, or sodden, taste savory and stirre up venery, for which purpose the people eate them much: the whitish pulpe or substance wherein these lye is of a pleasant taste but hard of disgestion, and breedeth that pestilent disease called *Mocxi*, if they be much or often eaten, or that they lye corrupted in the stomack: Those that grow in *Malabar* are accounted the best, and better then those of *Goa*; *Linschote* saith the two sorts hereof are called *Girasol* and *Chambasol*, but *Paludanus Barca* and *Papa*, and that those other names doe signifie the goodnesse or meannesse of wares.

*Iaaca vel Iaca.* The Diamond fashiond Chesnut Gourd.

## CHAP. CX.

*Cachi & Ciccara.* The Pine apple like Chesnut Melon.

THere is a prickly or thorny tree growing in *Malabar* which they call *Cachi* & the fruit thereof *Ciccara*, the tree is as great as a Fig tree, with Datelike leaves, and hard wood like Box, which they put to many uses: the fruit groweth not on the branches, but out of the body, and elder boughes as the true Sycamore or *Egiptian* Fig doth, and is a foote in length, of the thicknesse of ones thigh, and of a brownish yellow outside when it is ripe, being formed somewhat like a Pine apple, and having many severall cells or partitions within it as a Pomegarnet hath; the inner substance whereof is somewhat firme and well sented, but tasting like a Muske Melon, a Peach, a sweete Orrenge and hony together; these cells containe in them 250. or 300. small fruits in shape and taste like Figges without skinnes, within every of which fruit is another lesser, resembling a Chesnut, which is eaten roasted by the fire as Chesnuts are, and will cracke like them in the roasting.

## CHAP. CXI.

*Duriones.* The prickly fruitfull Melon.

THe *Duriones* may seeme the same with the former *Iaca*, because they come neare in some things but they much differ in others, as you shall perceive by this description. The tree groweth to be very great and tall, the Timber whereof is strong firme and sound, covered with a thicke ashcoloured barke, spreading plentifully into branches and store of fruit, having leaves that are somewhat long and pointed, dented about the edges, of a brownish greene colour on the upper side, and pale greene underneath: the flowers are of a pale or whitish yellow colour, and the fruite groweth to the bignesse of a Muske Melon, with a thicke greenish rinde set full of shorte and thicke but sharpe prickles, having some strakes thereon as the Melon hath: it hath within it being opened foure cells or divisions all the length of it, in every one of which lye three or foure white fruits as bigge as Hens egges (for if they containe five a peece they are not held to bee so good, neither yet if they looke yellowish, and not white they judge them spoiled by the wet falling into the chinkes) like unto the *Mangar blanco* of the *Spaniards*, but not so soft or muccilagie and taste like unto Creame, smelling somewhat sweet also: each of these fruits have enclosed within them a kernell like unto that of the Peach stone, which is somewhat long and insipide, yet making the throate harsh like unto an unripe Medler, and therefore are not eaten: These fruits are to be lightly troden on to breake them because of the prickes, which to them that never did smell them or eate of them before, may seeme to smell like rotten onions, but having tasted of them wil thinke them both to taste and smell better then other meats: for among the natives they are held in so good account that they thinke they can never be satisfied with them: but if any by eating too liberally of them shall feare to fall into a Surfeit, or to take any other harme by them, they shall be instantly helped and eased, if eyther they lay a leafe of *Betre* upon the stomack or eate some of the leaves thereof: for so great an antipathy there is between these two plants, that if some leaves of *Betre* be brought into a shippe or house, where these fruits are laydand kept, they will all rot and putrefie: so that it hath not beene knowne that any have taken harme by eating of them.

*Duriones.* The prickly fruitfull Melon.

## CHAP. CXII.

*Totocka Americana Pervana.* The Indian fruitfull Gourd bearing Almond, or the Indian Almonds of *Clusius*.

THe tree that beareth this fruite groweth very great and high, the body being bare of branches or leaves unto a very great height where it spreadeth into branches standing in compasse together almost like a Crowne, with faire great broad long leaves set on them greater than ones hand, somewhat like but much greater then those of *Diepanboome* of a darke greene colour on the upper side, and somewhat white or mealy underneath: the flowers breake forth among the leaves in severall places, and are of a darke greene colour, after which come the fruit, very great when it is ripe and round like a Bowle, but flat on one side whose shell is as hard as a bone, hardly admitting to bee bored or filed, and of a darke brownish colour dented in, striped and crumpled almost like unto Corke, so great that one can hardly compasse it with both ones hands and the fingers stretched out at length, the height also being neare the same size; this fruite in the inside is divided into six cells or particions by hard skinnes, in every one whereof is conteined eight, ten or twelve nuts lying orderly piled as it were one upon another, each of which are three square, somewhat

what long, and pointed more at one end then another, not so much rugged as the outer shell nor so hard but they may be crakt with the teeth, some of them greater then others, and all of them two or three inches in length, and an inch and a halfe in thicknesse, the kernell within being in taste not so like an Almond as a Walnut, more oily in a wet yeare then a dry, which the Indians by pricking sundry of them upon a sticke, and lighting of them, they will burne like a Torch to shew them their way, and continue long in burning, and give an Oily or Turpentine-like flame, having a blacke coale which turneth to ashes: The outer shell hereof is of the thicknesse of halfe an inch, containing within it a pint and a halfe of liquor *Antwerpe* measure, and weighed 17. ounces or more the emptie shell. The Indians seldome gather these fruites, but gather them after they are fallen, for they are afraid least they should fall upon their heads which were sufficient to beate out their braines, and when they are forced to passe them as in their warres, &c. they carry Bucklers over their heads to defend them. They make much account of these kernells, and use to eate them chiefly to provoke them to venery, whereunto they are too much proclive of themselves, and make it their chiefest felicitie having this proverbe with them *Pignean saccumâ pingean Totocka*, which is, *Si ambires venerem ede Totockam.* It groweth in high places and not in low grounds under the Line and on both sides thereof in the West Indies, and beareth fruit twise every yeare, that is, about *Aprill* and in *November*, and call it *Totocke*. It is very probable that this is *Clusius* his *Amydala Pervana*, as any by comparing that little he hath delivered thereof may soone determine.

*Totocka Americana sive Amygdala Pervana Clusii forte.* The Indian fruitfull Gourd bearing Almond, or the Indian Almonds of *Clusius*.

Many other fruites, as well Melon like as Gourde like and others, are used by the Indians and the Christians likewise living there among them in some sort, but these here mentioned are the choisest and chiefest of them; I will now therefore lastly shew you sundry other sorts of fruits of trees that have medecinall qualities for the most part in them, and so finish this worke.

## CHAP. CXIII.

*Pinei nuclei Maluccani.* Malucca Pine Kernells.

SOme Orchards in *Malabar* as well as the wild woods doe nourse up a certaine tree growing to the bignesse of a Peare tree, whose leaves are soft and tender, of a darke greene on the upper side and pale underneath, tasting very sharpe and biting upon the tongue for a good while, the fruite is of the bignesse of a Filberd and triangular, divided on the inside into sundry partitions, containing within them small white hard kernells, like unto the kernells of Pine apples, whereupon they have so called them, and which the Indians use as well in the cure of diseases, as to performe their wicked designes: they use to give two of these kernells, the skins that cover them being first taken away mixed up in a glister, to purge and procure ease to those that have the Sciatica or hip gout, & in the broth of a Chicken to those that have their urine stopped or make it with paine, and to cause tough, thicke and cold humours to be avoyded: they give them likewise to those that are short winded or have a cough, for which they much commend them, and often use them being dissolved in water, and the face or other parts of the body annointed therewith doth give helpe and heale Tetters, Ringwormes and Scabbes, being a little rubbed before the using, for they are causticke or burning as experience sheweth: Wicked women and harlots give foure graines or kernells of them to their husbands or others thereby to kill them: those of *Canara* doe call them *Gepala*, and are in frequent use with the Indians where they grow plentifully for purgations:

*Pinei Nuclei Maluccani.* Malucca Pine Kernels.

*Monardus* maketh mention of another kinde of purging Pine kernells, growing in *Hispaniola, &c.* within such like cones but greater and longer, thinner sheld and blacker then the usuall sort, whose kernells being white and sweete, tempt divers to eate of them without suspition of evacuation, yet five or six according to the ability of the patient, being given in wine doe purge strongly both upwards and downewards, avoyding grosse humours especially; but being a little terrefied at the fire they worke not so violently or with such torments and gripings:

*Lux let pinei a ij.*

## CHAP. CXIIII.

*Penoabson.* The Apple bearing poysonous Almond tree.

THevet sheweth in his description of *America*, that in some parts thereof there groweth a tree, the barke whereof is of a strange and mervailous sent, having leaves like unto Purslane, very thick and alwayes greene: it beareth fruite as great as large sised Apples, and as round as an hand-ball which are not to be eaten for they are poyson: but they containe within them six other fruits, very like unto Almonds but flatter and broader, each lying in a severall cell, which are wonderfull profitable to the people, to heale their wounds by darts or otherwise in their warres, for out of these fruits they presse a kind of red oyle with which they are quickly cured.

## CHAP. CXV.

*Cacao sive Cacavate.* The Peare bearing wholsome Almond tree.

BEnzo in his description of *America*, remembreth a tree growing in *Nicarragne* a Province of the West Indies somewhat like unto the last described, but because it is another sort you shall have the relation thereof as he setteth it downe. It is the fruite of a meane sised tree growing onely in warme and wet, yet shadowed places, and therefore must be defended from the sight of the Sunne by having a tall tree planted to the Sunne ward of it, which must be fitted and plashed that it may be as an Arbor unto it, or else it will wither and perish: the fruite doth somewhat nearely in forme resemble a Peare, or Peare fashioned Gourd, with a thicke shell or rinde, and within lyeth an Almond like fruite, halfe as big againe as a Walnut, inclosed in a hard round shell, the kernell being blackish without, and brownish ash coloured veines within, but bitterish and unpleasant, yet very sweete and pleasant to the Indians. After they have gathered the fruite they breake the outer rinde and lay the inner fruite upon Mats to dry in the Sunne, untill the moisture within them be consumed, and then they keepe them both for their meate and merchandise, for shippes loaden with them are carried from *Gnatimale* to new *Spaine*, and other places treabouts, and trucke with them for other commodities in stead of mony, and give of them to the poore in stead of an almes. A drinke likewise the Indians make thereof called *Chocolate*, well pleasing and accepted with the greatest among them, who account nothing of more esteeme; but to the Christians, at the first it seemeth a wash fitter for hogs, yet by use even accepted by them also in the want of better.

*Cacao sive Cacavate.*
The Peare bearing wholsome Almond tree.

## CHAP. CXVI.

*Areca sive Faufel seu Avellana Indiana versicolor.* The discoloured small Indian Nut.

THis tree groweth great and very tall, but the wood thereof is spongy and not easie to breake, without any branches unto a great height, and towards the toppe spreading many faire branches, and leaves thereon greater and longer then the Coker Nut tree, the flowers are white without sent, and grow many together on a long stalke hanging downewards from the lower branches, the fruit following on every one, being longer but smaller then the Nutmeg with all the outer rindes and shells, and hath the outer rinde covered with a yellow Cotton like silke, the inner kernell being very like unto a Nutmeg, somewhat round, and small at one end and flat at the other, with the like discoloured veines therein, but without any heate in taste or sent, and is therefore held to be cooling and drying: it groweth in sundry places of the Indies more or lesse plentifull in one or another place, and chiefly neare the Sea coasts: With the twigs hereof that are of two fingers thicknesse the Natives use to hunt the Crocodils as well in the water as on land, for if they can thrust these stickes into their mouthes they are sure they cannot breake them, because they are so lithye and spongy, and thereby they doe retaine and take them, it is called *Faufel* by the *Arabians*, but some falsly *Filfel*, by the chiefest Indians *Areca*, by those of *Gazarate*, and *Decan Supari*, in *Malabar Pac*, in *Malaca Pinan*, in *Couchin Chacani*: it is profitably used in all hot diseases, to helpe the tooth ach, and to fasten loose teeth in the head or the loose gummes: the Indians use this fruite abundantly eyther unripe to stupefie their senses like to drunkennesse, or ripe, being mixed with the leaves of Betell or

Betre

*Arecа vel faufel sive Avellana Indiana versicolor.*
The discoloured small Indian Nut.

*Nux Faufel cum suo in volucro et eodem exempto.*

*Betre*, the ribbes therein being first taken away, some put sundry other things to them, as *Lycium*, *Camphire*, *Lignum Aloes* and Ambegrise according to their qualities that take delight in it, which is generally through all the countries of India, with the chiefe persons most, and with the inferiour in some sort also. *Garcias* saith he distilled a water from them being fresh, which he used with good successe in all hot or chollericke fluxes of the belly.

*Arecа sive Avellanа Indicа versicoloris genus oblongum Clusij.*
A kind of small long discovered Indian Nut of *Clusius*.

*Clusius* in his *scholia* upon the *Faufel* of *Garcias* exhibiteth another kind of *Areca* or *Faufel*, whose kernells hath discoloured veines therein like a Nutmeg, or the former sort, and with a blacke covering over it, the chiefest difference from the other consisting in being longer then the other. *Lobel* supposeth it may be the kernell of a nut of his *Palma Pinus*.

*Linschoten* also saith that there is another sort of *Areca* which is smaller, blacker and harder then the former, and called by the Natives *Checaninas*, which causeth a lightnesse in the head.

*Clusius* also relateth of another as large as a Walnut, with the outer greene rinde, but the shell was hard and smooth of a Chesnut colour, long and pointed at both ends, flat on the one side and bunching out on the other, the kernell within being white and sweete. Another was about a finger long, and as thicke as two, flattish on the lower end, and of a rugged ash colour, the upper end being smooth and of a brownish colour, seeming like some small ticke, covered with a thicke hard shell, having a kernell within it.

*Arecа sive Avellanа Indicа versicoloris genus oblongum Clusij.*
A kind of long small Indian discoloured Nut.

Divers other fruits are mentioned by *Clusius* and many others wee have seene our selves, but bēcause wee doe not know any use of them or propertie in them, I rather forbeare their relating, then stuffe the worke with unprofitable matter, it being growne so voluminous already.

## CHAP. CXVII.

*Arbor Brasilia.* The Brassill tree.

THe tree that beareth the Brassill wood which serveth the Dyers use, and to make Inke is a goodly faire great tree growing in divers places of the countrey of *Brassill*, and in no other place as it is thought, and the chiefest about *Fernambuck* from whence have risen the appellations to the weod: the leaves wherewith it is cloathed are as small as Box leaves, thicke and evergreene like them, the barke is of an ash colour, and the wood red, especially the core or heart thereof which is the best, and as it is said is no bigger then a mans heigh, though the tree be so bigge in compasse that three men cannot fathome it. This as it is said also beareth neither fruit nor gum, but I wonder then how so many could be found growing there? could the earth of it selfe thinke you without seede bring forth that abundance? or will not time consume them all? surely it cannot be but that it beareth seede, and is thereby propagated although not observed &c.

*Arbor Brasilia.* The Brassill tree.

## CHAP. CXVIII.

*Arbor Tristis.* The sorrowfull tree.

THe tree that beareth this name from the properties riseth to be a reasonable tall, spreading sundry slender branches and faire leaves set by couples on them, very like unto the large or great Myrtle leaves and smaller then those of the Plum tree, little or nothing snipt about the edges, a little rough, and greene on the upper side and gray underneath: at each joynt with the leaves towards the ends of the branches on both sides come forth slender reddish yellow footstalkes wherewith they colour their broths and meates yellow like Saffron, bearing three or foure, or more flowers together thereon, composed of sundry small white leaves pointed at the ends, making a double flower, with divers small threds in the middle, smelling so sweet that they are thought to exceede eyther the Orrange or *Iasmine* flowers, whose propertie is never to blow open in the day time, but in the night onely (when its time of flowring is) for so soone as the Sunne shineth thereon in the morning, they all for the most part fall downe under the tree, and the whole tree with the branches seeme as withered and dead untill the evening, eyther through the tendernesse of the stalke, or by a naturall antipathy unto the Sunne, not to abide the shining face thereof, for some of the flowers doe abide on these branches that are most shadowed from the Sunne: the following fruite they give is flat somewhat like a Lupine with a thicke skinne, (it must be but small store, for what quantitie of fruite can this tree beare if all or the most of the flowers doe fall away) yet heart fashion, and of a greenish ash colour, with a division in the middle, in each part whereof is contained small flat beanes or kernells, like unto those of the sweet beane or Carob tree, heart fashion likewise, and covered with a greenish skinne or peeling, the inner kernell being white and somewhat bitter. This tree hath been much desired to be transplanted into our Christian world, but as some have sayd it would not abide, notwithstanding all the care of earthen and woodden vessells, wherein it was planted to be

*Arbor Tristis.* The sorrowfull tree.

brought

brought into *Spaine* or *Portugall*, neither ever would the seede spring as it is affirmed, but I have lately understood by a catalogue of the Plants growing in the garden of *Signor Corvino* of *Rome* that it groweth there, being one of the plants named therein. It plentifully groweth in *Malabar* and brought thence to *Goa*, and sundry other places of the *Indies*, where every branch being put into the ground will take roote and grow. It is called in *Malabar Mogli*, in *Malayo Singadi*, in *Decan Pul*, of the *Arabians Guart*, of the *Persians* and *Turkes Gul*, but at *Goa* and *Canarin Parizataco* from a certaine Nobleman so called (as the Natives thinke and therein very neare intimating one of *Ovids* fabulous metamorphosis) whose faire daughter the Sun having espyed fell in love withall, and having deflowred her & forsaken, for another, she slew her selfe; from whose ashes of her burnt carkasse rose up this tree, which is ever since ashamed to behold the face of the Sunne. In many places of the *Indies* they distill the flowers for their sweet sent sake, and keepe it for use; which in *Malabar* they call the water of *Mogli* after the trees name: the said water is good for sore eyes to coole their heate and redness, if linnen cloathes being dipped therein be layd upon them: the Indian Phisitions doe hold opinion that both flowers and fruite doe comfort the heart, and refresh the fainting spirits thereof, for they have some bitternesse in them. it hath not beene observed that the Indians apply this tree to any other use then is formerly expressed, and the colouring of their meates like as Saffron is used for the same purpose in *Spaine* and other countries.

## CHAP. CXIX.

*Arbor foliis ambulantibus.* Walking leaves.

NEare unto the Ile of *Cimbubon* and in the Ile it selfe, there groweth a tree bearing leaves like unto those of the Mulberry tree, having two small short and prickly feete as it were set on eyther side of them, which falling to the ground doe seeme as it were to creepe as if it were some living creature, and being touched by any will presently move it selfe. Master *Anthony Pigafetta* saith that he kept one of these leaves in a continuall motion in a platter for eight dayes (the motion whereof is likely to come by the ayre) and then it ceased.

## CHAP. CXX.

*Arbor aquam fundens.* The fountaine tree of water.

IN one of the Ilands of the *Canaries* called *Ferro*, there groweth a reasonable great but faire spread tree bearing leaves like unto Wallnut tree leaves but larger, abiding thereon and ever greene: it beareth fruite like unto an Ackorne hanging downe from the branches, which hath a kernell within of a very pleasant taste and almost like spice. In some parts of the world besides are found the like trees, the leaves whereof and branches doe perpetually droppe water (in the whole Iland there being no other water to be had) a thicke mist as it were or cloud encompassing it continually, except when the Sunne shineth bright thereon; which water being kept as it were in a fountaine made for the purpose to retaine it, serveth the whole Iland for their use. Our Countrey man Master *Lewis Iackson* dwelling in *Holburne*, told Master *Purchas* as he hath set it downe in his seventh booke of Pilgrimages Fol. 1639. that in the yeare 1618. he had beene in the said Iland *Ferro*, and had seene that tree, and saith it is as bigge as an Oake of a middle size, the barke white like Hardbeame, six or seven yards high with ragged boughes, the leafe like that of of the Bay, white underneath and green above: it beareth neither fruit nor flower: thus saith he, but it hath some other different relations which who so would see, let them reade the place before recited: the Ilanders call this tree *Garoe*, the *Spaniards Arbor Sancta*: but the ancient Historians call it *Til*. It is thought that *Solinus* and *Pliny* in his *lib 6.c. 32.* meant this Iland under the name of *Ombrion* and *Pluvialis*, for hee there saith that in the Iland *Ombrion* grow trees like unto *Ferula*, from whence water is wrunge out, from the blacke ones commeth bitter water and from the white that which is sweete and pleasant to drinke.

*Arbor aquam fundens.* The fountaine tree of water.

I might here insert the Barnacle tree but that it is found to be a fable, and that the Geese hatch their young as other Birds and fowles doe, and therefore I forbeare to speake of it.

*Arbor anatifera.* The Barnacle tree of the Goose.

## CHAP. CXXI.

*Quercus natalitijs Di virens.* The Christtide greene Oake.

IN the new Forrest in *Hampshiere* neare a place called the Castle of *Malwood* groweth an old great doating Oake, which by the relation of the neare Villagers, is alwayes observed to shoot forth fresh but small greene leaves every yeare a little before Christide, which abide not long thereon after that time, but fall away, others springing out in the due time that other Oakes doe, bearing both leaves and fruit as usually other Oakes doe in their season. King *Iames* in his time understanding of this tree, went and saw it, and caused it to be paled about and benches made thereat, both for people to sit and contemplate the wondrous workes of God therein, and to keepe unruly persons from breaking and spoyling it: but (*nitimur invetitum semper*) the more it was intended to be preserved, the more wilfull people were bent to breake and spoyle it (being the more famoused by that provision) and breake downe the pales and carry them away. I have had both leaves and Ackornes brought me from this tree, taken by Master *John Goodier* each in their season.

## CHAP. CXXII.

*Arbor Venereos stimulos domans.* The Chaste making tree.

PEtrus de Osina in his letter to *Monardus* maketh mention of a certaine tree growing there in the West Indies whose timber was of a spongie substance whereof the Indians would never take a sticke to burne, neither by any meanes, although they were treatned to death could be brought to burne it or abide where it was burned, for they said that whosoever came neare the fire or flame thereof, or whomsoever the smoake onely touched, was made utterly impotent and unabled to any venereous acts.

## CHAP. CXXIII.

*Arbor Farinifera.* The Bread tree.

SOme that accompanied Sir *Francis Drake* in compassing the whole world did relate that in the Iland of *Ternate*, which is neare the Equinoctiall line, towards the North pole groweth a strange kinde of tree about ten foot high, whose toppe is formed like unto a Cabbidge, in the middle whereof is found a fine white meale which the poore Ilanders gather, and by putting a little water thereto and letting it ferment they make past or dough, whereof they make thinne flat square Cakes, and bake them in certain long earthen pans, with fire put round about them which they eate while they are hot, for when they are growne older and hard, they steepe them in warme water, and bring them to a kinde of pultage and so eate them, but this Cake or bread is in a manner without taste or rellish, but when some Pepper or Cinamon with Sugar is put thereto, it is a pleasant food to many, but *Marcus Polus Venetus* recordeth a more strange bread tree growing in the kingdome of *Fanfur*, whose trunke two men could scarse fadome, the barke whereof being thicke, and taken away, the wood thereof about three inches thicke in compasse is as hard as Iron being so heavy tha it sinketh instantly in water, whereof the natives make them short pikes or speares sharpening and burning them at the end, so that they will be able to pearce Armour; but the whole middle of this tree is soft like unto a meale, which putting in water and stirring it to take away all the drosse that swimmeth above, they mould up the residence into cakes, and divers other sorts of viands fit to be eaten, and whereof as hee saith he brought some with him to *Venice*.

*Arbor vasta farinifera.*

## CHAP. CXXIIII.

*Arbor sive Palma succifera.*
The Bagge bearing Nut tree.

CErtaine *Dutch* Marriners having by a casualtie lost their shippe, wherein they with others were sayling to the West Indies, in their returne home, in their shippe boate lighted on a desart Iland called *Coronopez*, wherein they found whole woods full of these kindes of strange trees, and others growing among them whose fruits being round Nuts, as bigge as Wallnuts with their greene outer shell, and within them other smaller Nuts so round as a ball, and with so hard a shell, yet not very thicke that they could hardly be broken with an Iron hammer, and a white hollow kernell in the middle

tasting

tasting like Pease at the first, but a little bitter afterwards, like a Lupine, were inclosed in a long sheathe or hollow hose, resembling an *Hipocras* or Syrupe bagge, some being twenty two inches long, others two foot and a halfe long, yet all being very small at the end and growing larger up to the toppe, where they were about seven inches wide, and composed of a number of brownish threds or haires dispersed all over the case, some running at the length and some crossewise by a wonderfull worke of nature.

*Arbor sivepalma saccifera.* The bagge bearing Nut tree.

## CHAP. CXXV.

*Arbor metrosideros.* The Iron hearted tree.

SCaliger maketh mention of a certaine small tree, is reported to grow in the Ile of *Iava major*, whose heart or core is as impenitrable as Iron, from the bottome to the toppe: and the fruit which it beareth is likewise as hard, but the report saith he, is of so little credit and so neare a falsitie, as I am from beleeving it: yet *Nicholaus Costinus* in his Iournall doth report the same thing.

## CHAP. CXXVI.

*Arbor Gebuph.* The Splene tree of *Sumatra.*

IN the Ile of *Sumatra* anciently called *Trapobana* or *Taprobana* as *Thevet* relateth it, groweth a tree not very great, called there *Gebuph*, and in the Indies *Cobbam*, whose leaves are many smal ones set on a rib together, somewhat like unto the Cassia *solutiva*, or purging Cassia leaves, set on short branches covered with a yellowish barke: the fruit is somewhat thicke and as round as a ball, where under is contained a Nut as big as an hasel Nut, with a very bitter kernel within it, yet tasting like an Angellica roote; they use the fruit to quench thirst: but the bitter kernell is the most effectuall in the diseases of the Liver and Spleene, wherewith they are much afflicted, and therefore draw an oyle out of the kernells of the Nuts, which they take for eight dayes together, in which time the disease is much abated and quickly after cured: those that cannot by reason of the bitternesse take it so willingly, as women and children, it is appointed unto them to be annointed with the oyle on the belly, back bone and sides, which worketh the cure alike: the said oyle is in much use with them also, and of great account for the singular helpe and remedy it giveth to all joynt aches, gouts and the like: the gum likewise of this tree being dissolved with a little oyle and spread plasterwise is applyed to the grieved places with good effect. The inhabitants doe plant this tree neare their Houses in their Orchards and Gardens for to have the benefit thereof nigh at hand.

*Arbor Gebuph.* The Splene tree of *Sumatra.*

CHAP.

## CHAP. CXXVII.

*Beretinus fructus.* The Beretine Ackorne.

CLusius in his second booke of Exoticks and seventeenth Chapter, maketh mention that he obtained some of these fruites, from those that accompanied Sir *Francis Drake* in his Circumnavigation of the world, returning in the yeare 1580. by the meanes of some of his friends here, as Master *Garth* and Master *Morgan*, which were affirmed to be gathered in some Islands (whereinto they put both for fruit and victuall standing in neede of both) from very great and tall trees bigger then Oakes, whose leaves were like unto Bay leaves, not dented at all about the edges but thicke and shining: the fruit were like the Ackornes of the Ilex or evergreene Oake, but without any cup, for as hee saith he enquired thereof of some of them, whose outer rinde was thinne and of an ashcolour, and some blackish, the inner kernell being somewhat long and white, without any manifest taste within but covered with a thinne skinne, which they found good to be eaten without any harme following, and therefore in their want being taught by the Ilanders they boyled them like Pulse or Pease, and so eate them, or beate them to pouther and boiled them like Rice or Wheat, untill it became a pultage and so eate them for hunger: yet afterwards they found the like trees and fruit to grow in the Islands of the *Moluccas* as they affirmed: But with what other propertie they were indued, neyther they nor any other hath manifested to any that I know.

*Beretinus fructus.* The Beretine Acorne.

## CHAP. CXXVIII.

*Vhebebasou.* The Indian Hony tree.

THevet maketh mention of this tree among his other *American* singularities to be very tall, spreading the branches so uniformely, that it is a great pleasure to behold, in that they seeme so disposed by art and not by nature, having leaves on them like to Coleworts, (which I beleeve is mistaken, the figure not expressing such a forme) and fruit of a foot long. In the hollow parts of this tree above other, the Bees doe make their Hony and Wax, whereof the naturalls make much account, for with it they season their foode made of roots, &c. Vnto this tree resorteth familiarly a certaine beast somewhat like a Cat, but of a browne colour, called by them *Heyrat* that is the Hony beast to feed on the honey, which it carefully pulleth out with the feete without hurting the Bees or being stung or hurt by them.

*Vhebebasou.* The Indian Hony tree.

## CHAP. CXXIX.

*Pruna insana quæ Nuces insanæ a Clusio dicuntur.* Mad Indian Plums or Nuts.

THis Indian fruit mentioned by *Clusius* in second booke of Exoticks, page 53. and 54. is thus related by him. The *Dutch* after much wandring in the unknowne Seas fell by chance into a certaine Bay, scituate in 11. degrees 45. minuts of Northerly Latitude where they found certaine trees as big as Cherry trees, with long and narrow leaves like Peach leaves, whose fruits they saw the Monkies there eating, wherupon divers of them gathered some and eate them, which were fully round, growing for the most part singly each upon its stalke, and sometimes two together, being about two inches or not much more either longwise or round, with a firme but not very thicke shell, brownish on the outside and not very smooth, but smooth within, and of a brighter colour, containing a certaine fruit within somewhat like unto a blacke Sloe, both for forme and size, spotted with somewhat a large white spot at the bottome where it stood upon the stalke, having a stone under that Plum which was grayish and hard, and a kernell with it, those persons which had eaten of these Plums felt no harme, but some of the company steeping both stones and kernells, and boyling and eating of them fell into divers distemperatures, according to each mans severall humour, one thought his Cabin was made a Brewhouse, and bad take away the woman that was there: another called his Mates together, asking them if they would buy his fish, whereof he had varietie: another lying in his Cabin complained that his flesh was torne from his bones, another cryed out loudly that they were building a great ship in his Cabin, another in his Cabin broke foure or five *Chinay* dishes, saying that many men were comming to take away his Cabin from him, another calling to the Maister of the shippe said, doe yee not see the Divell sitting in the Sterne catching Fish; another sayd that he saw the Anchors in the bottome of the Sea through the bulke of the Shippe; the Masters sonne said to his father, O my father I see a number of little men running upon your nose, but after they had slept all these imaginations vanished, yet some of them slept for a day and a halfe, and some two whole dayes before they waked, and some thereby were troubled with the laske: many other fancies fell among the rest which were too long to recite; but among them all saith he as it were in scorne among the rest there was an English man distracted, who looking upward said he saw the heavens open and cryed with a loud voyce, O Lord I will willingly follow thee, and with divers other gestures moved the company to laughter. *Clusius* sheweth that in the same table with these Plums or Nuts hee set another small Nut not much unlike an Hasell nut which made no noyse of any kernell therein, and knew not whether it had any cup to hold it as an Acknorne hath or no.

*Pruna insana quæ Nuces insanæ a Clusio dicuntur.* Indian Plums oe Nuts.

## CHAP. CXXX.

*Mamoera mas & fœmina.*
The male and female Dugge tree.

THe forme of these two sorts of tres are both alike, not differing the one from the other, but in this that the male beareth no blossomes, but fruite like unto a small Pompion many growing together towards the toppe out of the body of the tree which hath no armes or branches but onely large broad leaves much like unto the Plane tree or Maple tree leafe, each standing on a very long stalke: the trunke or stocke of the tree is neare two foot thicke, and about nine foote high: the flowers are of a pale yellow colour like unto Elder blossomes which serve to no use, the fruit is round and fleshy, yellowish when it is ripe, and serving them to loosen the belly when they are eaten and conteine within them many round blacke shining graines as bigge as Pease which likewise are put to no use with them. The propertie of these trees is said to be, that unlesse the male kinde bee planted to grow neare the female it will beare no fruit at all; of which nature a kinde of Date tree is said to be also. This tree groweth in that part of *Brassill* that the *Portugalls* called *Baya de todos los Sanctos.*

*Mamoera mas & fœmina.* The male Dugge tree.

CHAP.

## CHAP. CXXXI.

*Moringa.* The Bezar tree.

*Moringa.* The Bezar tree.

THis tree groweth not great, nor spreadeth with many branches, but is like unto the Lentiske or Masticke tree both for greatnesse and leaves, being full of knots, very easie to be broken, of a very faire but sad greene colour and of the taste of Turnip leaves: the fruit is a foot long, and of the bignesse of a Reddish root having eight edges or corners of a greenish ashcolour with a white substance within devided into certaine cells wherein lye small round seede like unto small Pease but greene and tender, and of a sharper taste then the leaves: the whole fruit sliced in peeces is boyled in the broth of flesh and sundry other wayes. But the roote of this tree is a soveraigne Antidote or Counterpoison, as effectuall as Vnicornes horne or Bezar stone or any Treakle, for the natives doe usually take thereof, both against all kindes of poisons and the bitings of the most venomous creatures, yea even that serpent which the *Portugalls* call *Culebras de capillo*, which is accounted the most dangerous of all, taking thereof both inwardly and applying it to the outward place. They have found it also to bee singular good against the winde chollick, and to be no lesse effectuall against the Leprosie, for many have beene thereof cured by often using of it, it is mixed also with those medecines that purge melancholy. It groweth plentifully in all the Province of *Malabar*, where they bring the fruit into the market to sell as beanes and pease or elsewhere. The *Arabians* and *Turkes* call it *Morian*, the *Persians Tame*, but they of *Gazurate Turiaa*.

## CHAP. CXXXII.

*Negundo mas & fœmina.*
The male and female wound tree.

*Negundo mas.* The Male wound tree of the *Portugals*.

THe Indians make two sorts hereof, the one they call *Varolo Nigundo*, that is, the male, and the other *Niergundo* the female, in *Malabar Noche*, in *Balagate Sambali*, in *Decæn Beche*, and so also by the *Persians* and *Arabians*, but *Ait* by the *Turkes*, and *Norcila* by the *Portugalls*: these trees are of much esteeme in the province of *Malabar*, and of so frequent use with all sorts of people, for all their griefes and diseases, that if they were not great increasers, and that every branch thrust into the ground will take roote and grow, they had beene wholly consumed or growne so scarse that they would have beene at an exceeding great price. The male groweth like the Almond tree with rough leaves like unto Sage, greene above and hoary underneath, and dented about the edges, somewhat resembling Elder leaves a farre of. The female kind groweth greater and hath larger and rounder leaves, resembling those of the white Poplar tree and not dented about the edges: the leaves of both sorts smell and taste like Sage, but yet are more sharpe and bitter, many of them having a white froth on the backside of them, comming on them in the night: the flowers of both are of a pale blew or ashcolour much like unto those of Rosemary: the fruit of both likewise is like unto blacke Pepper but nothing so sharpe and hot as Pepper comming nearer unto the taste of Ginger. Both leaves flowers and fruit bruised and boyled in water or oyle are usually applyed to

all

all diseases by the vulgar sort, but especially to all joynt aches, tumours and contusions proceeding from any hot cause, and that with singular good effect: the leaves also bruised and laid upon old Vlcers doth wondrously helpe to digest the matter, cleanse them and bring them to cicatrising, so as the body be not foule but prepared and purged before hand. And certainly they are found so available in all wounds, Impostumes and bruises, that the people using these, seeke for no Chirurgian. The women use to wash their whole bodies with the decoction of these leaves at all times and seasons, and are so perswaded of their effect to helpe them to conceive children, that they that should goe about to perswade them the contrary, they would stone them to death.

## CHAP. CXXXIII.

*Nimbo.* Another healing or wound tree.

THis other tree is more rare and scarse then the last, called by those of the countries in *India* where it is knowne *Nimbo*, but by those of *Malabar Bepole*, and is of much account both with the Christians there and Gentiles. It is as bigge as an Ash, whereunto a farre off it is very like, the leaves are very greene on both sides, dented about the edges and pointed at the ends, it is plentifully stored with both leaves and flowers which are small and white, with five leaves apeece and some yellow threads in the middle, and of the smell of the *Trifolium odoratum*, sweet Trefoile, after which the fruit appeareth which are like unto small Ollives with a yellow thin skinne. The leaves are somewhat bitter, but very wholesome being bruised and mixed with a little juice of Lemons, & dropped into foule Vlcers or those that are hollow or fistulous, or with hard skins therein eyther of man or beast, doth helpe them by digesting, clensing, healing and skinning them: the juice of the leaves is a most familiar and knowne remedy in *Malabar* to kill the wormes of all sorts in the body, whereunto they are much subject, whether taken alone or with other things for the purpose into the body, or used outwardly to the Navell: the flowers & fruit also are much used against the gout and the paines, swellings, weakenesse and Impostumations of the joynts or parts, the Oyle likewise pressed out of the fruit is singular good in the paines and greefes of the sinewes, and therewith doe those of *Malabar* cure both wounds in the flesh, punctures and pricking of the Nerves and Sinewes, and contractions or distortions of the members.

*Nimbo.* Another healing or wound tree.

## CHAP. CXXXIIII.

*Hyvourahe.* The *Americans* vice Guajacum.

THis tree is very tall having a barke of a whitish silverlike colour, but the wood is reddish under it of a little brackish or salt sweet taste, resembling the wooddy part of *Licoris*: it beareth fruite of the bignesse of a meane Plum, and of a good yellow colour, with a kernell within it, of a most sweet and delicate taste: but which maketh it the more wonderfull, so seldome bearing fruit that as it is said, a man in his life time shall scarse see the fruit above foure or five times on the tree, being fifteene yeares betweene one and the others bearing. The barke of this tree is of a wonderfull vertue and effect in curing the Indian (which we call the *French*) disease and is of the same account with the Indians where it groweth that Guajacum is with us, and while it is fresh cut or peeled from the tree giveth a white milke, this barke being cut in slices, they boyle in water three or foure houres untill it become of a Claret wine colour, which decoction they drinke for fifteene or twentie dayes together, using in the meane time a spare diet, by which meanes they are not onely cured of that disease but of any other that proceedeth of cold and flegmaticke humours: the kernell of the fruit is much used by the sick whose appetite is lost to quicken it and get it againe. Neare all the coasts of the continent saith *Monardus*, is gathered by the *Indians* a certaine white liquor like milke taken from the branches, and small Apple like trees being wounded, which they call *Pinipinichi*, which soone groweth thicke, and is somewhat clammy, three or foure drops whereof being taken purgeth very violently, being taken in wine: but if any finde it to worke above their strength or desire, by taking eyther a little broth, wine or other drinke, it stayeth the working presently. *Lat. Pinipinichi.*

CHAP.

## CHAP. CXXXV.

*Achanaca Treveti.* The blacke Moores Guajacum.

THe *Ethiopians* on both sides of the River *Senaga*, neare unto *Cape verd* as *Thevet* saith, doe abound with the Venereous disease, which holdeth them chiefly in the privie members which in men is called *Asab*, in women *Asabates*, the disease it selfe *Borozail* or *Zail*: but by the skill of the Phisitions of whom they have many, and skilfull in their profession called *Biarins*, they have found out growing with them an herbe of assured helpe and remedy therefore, which groweth up with a great stalke as bigge as a mans legge, and many great leaves thereon, cut in or jagged on both edges, somewhat resembling a Colewort leafe, but nothing so thicke eyther in the leafe or middle ribbe and double pointed at the end, from among whom groweth the fruit, of the bignesse of an egge, and of a yellow colour, which they call *Alfard*, the decoction of this herbe above all others, although they use divers, is of sufficient validitie to cure it, for they have no other Guajacum for their helpe, and therefore use this in stead thereof.

*Achanaca Theveti.* The *Ethiopian* vice Guajacum.

## CHAP. CXXXVI.

*Winteranus cortex.* Captaine *Winters* Cinamon.

CAptaine *William Winter* that in a shippe by himselfe accompanied Sir *Francis Drake* in part of his voyage over the whole world, but left him at the *Straights* of *Nagellon* returning from thence home into *England* againe in the yeare 1579. in the parts thereabouts cut downe certaine trees, whose barke was somewhat like unto the thicker sort of Cinamon, both for substance and colour, yet for the most part thicker, and some of it of an ash colour, and some brownish on the outside and rugged like Elme barke, some of it having chinkes or riftes on the inside, and some smooth and firme, of a smell not unpleasant, but of a very sharpe taste like many spices together, heating the mouth more then Pepper; the leafe of the tree is of a whitish greene, not unlike the Aspen leafe, the berries grow in clusters like the Hawthorne, with divers seedes in each of them. They at the first knew not of any properties therein, and therefore boyled some of it in hony, to make it the more pleasant to be taken and dryed other some and made it into pouther, putting it in stead of Cinamon in their meats: but afterwards they found it to be singular good against the Scurvey, for divers in the shippe being troubled with that disease found remedy thereby in using it a while. Some of our company of Apothecaries, and those not of the meanest doe use to call the *Canella alba* mentioned here before *Cortex Winterani*, and have used it in their dispensation of *Mithridatium* as a substitute for *Costus*, whereof I gave you a touch in the Classis of *Cardui* and *Spinosæ*, in the last Chapter thereof save one, but now by comparing the one with the other you may easily see the errour, for the *Canella alba* is a white barke, rowled like Cinamon, and not much thicker then it,

*Winteranus Cortex.* Captaine *Winters* Cinamon.

of

of an hot taste but neither like Cinamon nor Pepper, and this *Cortex Winteranus* is thicker then the thickest Cinamon, not caste into rowles or hollow pipes like it, and tasting much quicker, besides the colour is of a duskie browne in most, comming neareſt unto Cinamon, I thought good a little to explaine this matter here, becauſe I finde many poſſeſſed ſo ſtrongly with that errour that *Canella alba* is *Cortex Winterani*, that all may ſee how true their opinion is. This barke might ſeeme to be that whereof *Monardus* ſaith he had a peece from *Bernardino de Burgo* an Apothecary, but that his had a more excellent ſmell and taste, excelling that of the Nutmeg, and as pleaſant as Cinamon, and more cordiall, which is not found in this barke of *Winters*, *Monardus* likewiſe maketh mention of another thicke barke which was taken from a tree as great as an Elme and like in forme, growing ſcarſe in any other part of the Weſt Indies, then neare the Rivers ſides about 25. leagues diſtant from *Lima*: it is hot ſaith he above the ſecond degree: the Indians uſe to put it up into their noſtrills, the fine pouther of the barke when they are troubled with rheumes and defluxions from the braines, or with other paines in the head, for it plentifully draweth downe humors whereby they finde eaſe.

## CHAP. CXXXVII.

*Coru arbor.* The coſtive or binding tree.

THis tree ſomewhat like unto a dwarfe Orrenge tree both for forme and leafe, but having a thicker middle ribbe and eight or nine other ſmaller ones running to the ſides: the flower is yellow without ſent, the barke of the roote onely is in uſe which is of a pale greene colour, and being broken yeeldeth much milke, which is ſomewhat clammy, having little taſte, but ſome bitterneſſe; & is more drying then cooling. The juice or milke of the barke of the rootes hereof, although unpleaſant is much uſed by the natives of *China*, *Japan*, *Malaca* and *Bengala* as well as *Chriſtians* in all manner of Fluxes and Laskes comming from what cauſe ſoever. Thoſe of *Canarin* call it *Coru*, they of *Malabar Curo* and *Curo dapala*, and the *Brachmenes Cura*.

## CHAP. CXXXVIII.

*Pavate.* Another Coſtive tree.

THis other tree which is more frequent to be had then the laſt, and called *Pavate* in *Malabar* is therefore in more uſe though not altogether of ſo ſtrong and ſpeedy effect, for the ſtaying of Laskes and Fluxes, but is of excellent propertie to coole all hot inflammations, and eruptions of cholericke matter in the skinne and S. *Anthonies* fire: the roote of this tree is of chiefeſt uſe, and ſometimes the wood ſteeped in the decoction of Rice, which will grow ſower after it hath ſtood a few houres, and then they call it *Cania*, with this decoction they waſh alſo the outward parts inflamed or ſpotted which cooleth much, and helpeth all thoſe heates: it is alſo drunke being ſteeped as aforeſaid againſt the heate of the Liver, and in hot Fevers: a few leaves of Tamarinds being put thereto they uſe to waſh the ſides of Vlcers and wounds that are inflamed, and have defluxions of humours to them to ſtay the Flux and coole the heate. The tree is not greater then the former, having but few branches and ſuch like leaves of the Orrenge, but without that ſmall leafe underneath it, and of a freſh greene colour: the flowers are whitiſh like unto the Hony ſuckle with ſmall round blackiſh ſeede likeunto thoſe of the Maſticke tree: the barke is of an Aſh-colour, and the root white. The *Brackmenes* and thoſe of *Canarin* call it *Vaſavelì*, the *Portugalls Arbol contra las eriſipolas*.

*Pavate.* Another Coſtive tree.

## CHAP. CXXXIX.

*Pacal.* The Tetter tree.

THis tree groweth neare the Rivers ſides in the Weſt Indies, part whereof being ſent to *Monardus* had this commendations that the aſhes of the wood mixed with a little Sope, the Indians uſed to annoint on thoſe places that had Tetters, Ring-Wormes or the fowleſt ſpreading Vlcers, and ſcarres that could be, either in the head or any other part of the body to cure them and leave the place faire againe.

## CHAP. CXL.

*Lignum Nephriticum.* The tree againſt the ſtone.

FRom *Hiſpaniola* and the parts thereabouts hath beene often ſent many yeares ſince as well as of late, though now in farre leſſe eſteeme, a certaine ſmooth light and white wood, the tree whereof is as bigge as a Peare tree, without knots: the wood being ſliced ſmal and put to ſteepe in pure Conduit or Spring water will within halfe an houre, or thereabouts (if it be right) diſcolour the water into a fine light blew colour, which lying longer therein will cauſe it grow of a deeper colour, this infuſion ſo made, although it be altogether inſipide and without any taſte, as if nothing had beene put into the water, is found yet to be hot and dry in the firſt degree, and ſingular availeable againſt the ſtone in the kidneyes and the difficultie in making urine, and is found alſo by good experience to open the obſtructions of the Liver and Spleene, the water or infuſion is being drunke of it ſelfe, or mixed with wine and ſo taken: but there is another wood very like unto this, which often obtruded on many in ſtead thereof which, being infuſed in water in the like manner will diſcolour the water yellow, and therefore without tryall the right is hard to be diſcerned.

## CHAP. CXLI.

*Lignum Moluccenſe.* The Moluceas tree againſt venome and poyſon.

IN the Ilands of the *Moluceas* is a certaine tree rather planted every where in Orchards then growing naturally being as bigge as a Quince tree, whoſe leaves are broad and cut into diſivions, ſomewhat like unto thoſe of the Mallow, the fruit is like to Haſell nuts but leſſer, and with a ſofter and blacker ſhell, whereof the natives make ſo great account that they will ſcarſe ſuffer any ſtrangers to ſee it, much leſſe to know any of the properties of it, which they keepe from others as ſecret as may be: but yet this their ſecreſie hath cauſed it to be ſought for and ſearched into nearer then otherwiſe peradventure it would have beene: For ſome *Portugalls* have found out in part by the ſight of the cures the Indians performed, and partly by their relations, which by meanes they made unto them they obtained of them, and partly by their owne judgement and practiſe alſo at ſundry times in the Spittles there, and in the ſhippes among Mariners, that the wood made into pouther and taken in a convenient quantitie, according to the ſtrength of the venome and the patient that ſhall take it, ſo as the quantitie for a time exceede not ten graines taken in broth or water, or other liquor, is a moſt certaine ſpeedy remedy againſt the venome of the moſt virulent Serpents that are, even the Viper *Regulus* (that is a Serpent that hath like a cappe or crowne on the head) the *Aſpis* or any other, and the pouther ſtrewed on the bitten place: they uſe to file the wood ſmall either with the Sea dogges skinne, or a fine Iron file: in the ſame manner likewiſe they give halfe a ſcruple of the pouther in warme water, or the broth of a Chicken or Hen to them that are wounded with poiſoned arrowes, which they much uſe one againſt another and put on the pouther into the wound: being taken in the morning betimes faſting, having made a ſpare ſupper over night before: it helpeth to evacuate all tough thicke and melancholy humors, and herebe helpeth quartaine and quotidian Agues, prevaileth againſt the Iliacke and Chollick paſſions of winde or humors, the dropſie alſo, the gravell and ſtone in the backe or kidneyes, the difficultie of urine and the moſt cruell chollerick paſſion, and other old griefes likewiſe in the joynts and legges, as well ſchirrous as ſcrophulous, that is, have hard ſwellings or nodes and knots in them, the ſame alſo killeth the wormes in the body of all ſorts: it regaineth a dejected or loſt appetite, and if the purgation worke too fiercely upon any, to the patient is given halfe a ſmall cup full of *Cania* (that is the decoction of Rice) to ſtay the working ſuddenly, or elſe by eating a ſmall Birde, ſo that it is in the Phiſitions or the Patients power to be purged as much as they will: by the taking of this medecine there not hath bin found any trouble to the ſtomack, or other ill ſymptomes, although taken without obſerving any diet, or defraining their buſineſſe abroad, yea in the working thereof living moſt looſely: it is obſerved likewiſe to be avaleable in the old paines and griefes of the head, the Megrime, Falling ſickneſſe and Apoplexye, in the diſeaſes of the belly and wombe, as alſo the ſhortneſſe of breath, the noyſe and ſingings in the eares, and the goute or joynt aches; it is given in all ſeaſons to all ages to differing natures or diſpoſitions, and that without eyther danger or trouble: but that onely in chollerick perſons and that have hot ſtomackes and Livers, it breedeth ſome perturbations in them untill that they have taken ſome meate, and inſome it hath procured a vomit; but to the hot and chollericke perſons being given with the Syrupe of Vinegar, or in the fruit of a Charambola being preſerved, or in a Pill with Conſerve of Roſes, it taketh away all thoſe troubles. In ſome alſo it cauſeth an itch in the fundament, and ſometimes excoriation, and the Piles alſo in ſome, but very few, which are ſoone helped by other remedies. Theſe cures have beene often performed, and yet the Indians performe many other no doubt, which they conceale from the Chriſtians all that they can. This wood is called by them *Panava*, the ſeede hereof is much uſed through all the Provences of the Indies to catch birds, being carryed thither to bee ſold, for ſome thereof mixed with boiled Rice and caſt to the wild Birds cauſeth as many as take it to fall downe to the ground, as being ſtoned for a time, but if any take thereof too greedily, it will kill them if they bee not helped by cold water put on their heads, but Dawes above all other Birds are ſooneſt kild hereby.

## CHAP. CXLII.

### *Lignum Colubrinum.* Snake wood.

THere are divers sorts of Snake woods, *Acosta* hath set forth two or three, that he knew used by the Indians against the bitings of Vipers, Water Snakes, or the like Serpents, and yet as *Clusius* saith none of those agreeth with these three that *Garcias* maketh mention of, *Bauhinus* calleth them all *Clematis Indica*. The first of *Garcias* is rather a roote then a wood, and groweth with foure or five slender branches, about two foote high, the leaves are like Peach leaves, but more shining, the flowers grow many together on a long stalke in clusters, of a brave red colour, the berries are like those of the Elder, clustering together, and red and hard. The roote, which is most in use, is full of knots or heads, growing above ground, with many small strings under them, being of a whitish ash-colour, and of a firme substance, with a little bitternesse in the taste: it is called by the Inhabitants *Lametal*, and by the *Portugals Pao da cobra*, that is Snakewood: This roote being beaten into pouther is given in wine or some cordiall water to those that are bitten by any Serpent, and likewise taketh away spots and pushes, or wheales, or other fretting sores in the skinne, and is held to be good against that cruell disease, which they call *Mordexi*, and some take to be Plague, or other dangerous infectious disease, and some call it the Chollericke passion, it is held also to be good against agues, an ounce thereof bruised and steeped in water, purging much choller by vomit. His second sort as he saith when it standeth alone, groweth to be a tree, and is like the Pomegarnet tree, set with thicke, short, and hard thornes, with a whitish thicke and firme barke, full of rifts, and a little bitter, but not so much as the former, the leaves are of a yellowish greene colour, very pleasant to behold: but if it grow by any other tree, it will clime thereon by the branches unto the toppe like a Gourd: they use to give both the wood and the barke hereof, but especially the roote in the same manner aforesaid, and for the said purposes: it groweth in the Isle of *Goa*. His third sort was brought to the Vice Roy, in certaine small bundles of wood with their rootes to them, being slender, hard, blacke and sweete smelling, which rootes they of *Iasana patan*, being an Isle nigh unto *Zeilan*, did wonderfully commend against venome or poyson. It groweth up with a few slender branches, foure or five cubits long, which if they be not tyed or held up will lye on the ground, having a few thinne long leaves like unto those of the Masticke tree for the forme, yet not greene but spotted, with whitish blacke markes upon them. The first of these as *Garcias* saith, was found to be effectuall against the venome of those virulent Serpents, by this meanes. They have there breeding with them, a certaine small beast, as great as a Ferret, which they call *Quil*, or *Quirpole*, being a deadly enemy unto the Serpent *Reguluis*, with whom when soever it fighteth, it eateth of the heads of one of those rootes, that is bare above ground, which having chewed, he casteth his spittle upon his head, and over the rest of his body, and his fore feet also, and then fighteth with that serpent, and will not leave it untill he have

*Garzia primum.*

*Secundum.*

*Tertium.*

*Lignum Colubrinum primum Acostæ.*
*Acosta* his first Snake wood.

*Lignum Colubrinum secundum Acostæ.*
*Acosta* his second Snake wood.

killed it. Many *Portugalls* at severall times have beene eye witnesses to these battels: for they not onely keepe this small creature in their houses, to sport themselves with these combates, but to kill their Mice, whom they most eagerly hunt and kill. There are also certaine wandring beggers called *Jogues* who doe often carry about with them these serpents *Regulus* tame, making men beleeve they have enchanted them, and some likewise that are fierce, whom for a reward they will suffer these Ferret-like beasts to fight with.

*Lignum Colubrinum primum Acostæ.* *Acosta* his first Snake wood.

The first sort of Snake wood that *Acosta* maketh mention of, groweth in *Malabar*, somewhat after the manner of Ivy, spotted like unto the stalke of Dragons, and so like unto a serpent, that he that should see it at the first, not having seene it before, would take it for a very serpent, especially beholding it in the Moone light. The first leaves it hath are broad, and whole without any cut or devision on the edge, but those that come after are like allmost unto Bryony leaves with a ribbe in the middle of them, and five or six others, running from thence to the edges, and lastly, some cut into divisions like a Vine leafe, all these sorts of leaves being to be seene at one time on the stemmes and branches, that they would seeme not to be the leaves of one and the same plant: This wood is held to be the most soveraigne remedy against the venome of all sorts of serpents wherewith they abound, that by the onely sent thereof, carrying it continually about them, the serpents will flye from them as they walke in the fields, and if they doe touch any of them therewith, it will make them to breake in peeces and dye.

*Lignum Colubrinum secundum Acostæ.* *Acosta* his second Snake wood.

Another sort groweth low and small, having onely three leaves set together, which are soft, long, and narrow, smooth, and of a darke greene colour, it hath not beene knowne to beare either flower or fruite; the roote is long and slender, smaller then ones little finger, running along under the surface of the ground, and knotted in divers places, the outer rinde being very thin and of an ash-colour, having at the first little or no taste therein at all, but after a while it yeeldeth a fine sent and taste like Muske, this barke chappeth in many places, shewing under it another thicker, and yellow, of the sent of *Trifolium odoratum*, Sweete Trefoile, and tasting sweete like Licoris, but not abiding long, the substance whereof is wooddy, and called in *Canarin*, *Duda Sali*: this roote being beaten into pouther and taken in Wine or Water, is said to be a certaine and present remedy against the bitings and venome of any serpent whatsoever: it is much used likewise in tertian and day agues, the weakenesse of the stomacke, the trembling and passions of the heart, or swounings, and against all sorts or poysons: many have affirmed that no serpent had power to doe him harme that but held it in his hand, and that the sight thereof would make the serpents flye from it to some other place: it is held also to be good for those that have stinking breathes, or have stincking foule hollow teeth that give an evill savour, to hold it in their mouthes, or to put it into the hollowness of the tooth.

A third sort is found in the same Provinces, and is a tree of a very large size and greatnesse, whereof peradventure that was a peece that *Clusius* saith he had of Doctor *Hector Nunes*, the *Portugall* Physition here at *London*, the wood being like a peece of Ash, firme or close, with certaine veines running therein, the rinde or outer barke being of a whitish ash-colour, and tasting somewhat bitter.

## CHAP. CXLIII.

### *Cohyne.* The Indians rattling God.

THe *Portugals* possesse a certain Country in *America*, called *Morpian*, which is ful of very good fruits, and among the rest the *Nana* or *Pinas*. There is also growing a tree whose fruite they call *Cohyne*, having leaves like to those of the Bay tree, and fruit as bigge as a Melon, formed like unto an Estridge egge, which although it is not eaten by any of them yet is very beautifull hanging on the tree The Savages use to make drinking cuppes of them, but besides that they commit Idolatry there with, which is wonderfull, and to be lamented, for having emptyed and made hollow these fruites, they fill them with the seedes of *Milium* or some other thing, which being shaken with ones hand, or with the winde, will make a noyse: then doe they fasten a pole into the ground, and sticke this fruite full of those seede on the toppe thereof, and fasten about it the most beautifull feathers of birdes they can get: Every house hath two or three of these fruits decked up in this manner sticking on the poles, which they have in great reverence, thinking some god to be in them, because when they are shaken they make a noyse and their priests aud prophets make them beleeve their God, whom they call *Toupan*, speaketh and telleth them what they should doe, and what shall come to passe, and it is not to be found that they worship any other thing, *Clusius* saith that this fruite is called *Maraka*, and *Tamaraka*; but I thinke these names smell somewhat of a

*Cohyne.* The Indian ratling God.

Greeke

Greeke Godfather, as the *Tamalabathra* from *Tamalapatra*: yet others say they are their hand-rattles wherewith they dance.

## CHAP. CXLIV.

*Palma Hairi.* The thorny *American* Palme tree.

THis tree groweth in some parts of *America*, both in shape of body and leaves like unto the Date tree, but full of sharpe thornes, bearing fruite as bigge as an hand-ball, but pointed at one end, having within it a fine snow white kernell: the wood of this tree is as blacke as blacke marble, and sincketh in water because of the heavinesse, and therefore some have thought it to be Ebony, but *Thevet* contradicteth that opinion with these reasons: first that Ebony is a wood more blacke or shining, and then that Ebony beareth no thornes, and lastly, Ebony is not found in *America*, but in *Ethiopia*, and the East Indies, about *Calecut*, *&c.* The Indians of this wood make them swords, which for the massinesse give a mighty blow, and will breake both scull and bones, where it lighteth on any, although it doth not cut as our swords doe: they make also arrowes of them, which by reason of their hardnesse like iron, and the points of them burned, to make them so penitrable, that they will be able to pierce a good corselet.

*Palma Hairi.* The thorny American Palme tree.

## CHAP. CXLV.

*Palma scriptoria & aliæ arbores, cujus folia & cortices chartæ vicem præbent.*
The writing Palme tree and sundry others, whose leaves and barkes have supplyed the office and want of Paper.

THere are sundry sorts of trees growing both in the East and West Indies (although none of the Nations of the West Indians, except the *Mexicanes* know any use of writing, or Letters, before the *Spaniards* first entrance among them, but the *Spaniards* there made use of divers in the want of paper) whose leaves and barkes have beene used to write on (besides the ancient paper Reed, which served the former Greekes and Latines to that purpose for many ages, whereof *Pliny* hath largely intreated, and *Guilandinus* as largely commented upon him, and whereof I have entreated also in another place of this Worke) as namely sundry dwarse Date trees, whose leaves have so smooth a surface that they served them very finely to write on, that is, with a small pointed iron, to engrave their characters herein. There is also growing in the Country of *Mangi*, which is neere the *Tartars* and *Chineses*, a certaine tree called *Tal*, and *Vguetal*, whose leaves are very large, and through all those Countries are used to be written on: it beareth fruite like unto great Turneps, whose meate under the outer rinde or barke is tender, sweete and edible. *Oviedus* maketh mention of two certaine trees growing in *Hispaniola*, the lesser called *Guajabara* by the Indians, and by the *Spaniards Vuero*, because the fruite thereof are like Grapes: the wood whereof is reddish, sound, and thicke, and fit to make coales, it beareth the fruite more loosely separate in sunder then the Grape, and of the colour of the Mulberry or Rose, having little substance thereon to be eaten, for they be as great as an Hasell Nut, and a stone within it is almost as great: the leaves of this tree are broad

*Palma humilis scriptoria.*

*Tal.*

*Guajabara.*

broad and round, as bigge as the palme of ones hand, as thicke as two Ivy leaves, and greene, and sometimes reddish, whereon the *Spaniards* used to write with an iron pen or pointell on both sides of the leaves, but they must be fresh gathered and presently written upon, which Letters then will appeare white, in the greene or reddish leaves that they may be easily read, notwithstanding the middle ribbe, and the other veines therein, in that they will not hinder ones hand very much. The other tree they call *Copey*, growing greater and taller, whose leaves are round like unto the other, but twice as large and thicke as they, and therefore better to write on, the middle ribbe and veines being also smaller, and thereby hindering the pointell from the graving thereon so much the lesse: these leaves also the *Spaniards* made use of for playing cards, engraving the formes of Kings, Queenes, &c. thereon, and would not easily be broken. *Nicholaus Costinus* in his journall setteth downe that neere the City *Cael* where pearles are found, there groweth a tree, whose leaves are so large that two or three men may be kept dry in their journeyes, having one of them spread to cover them, for they are of sixe braces or fathomes in length, and as many in breadth, which leaves also serve them very fitly to write upon, each of them being so thinne and plyable withall, that being foulded up handsomely together, one may carry one of them in their hand. *Duret* also among his admirable plants remembreth the *Melt* or *Mangey* of the *Mexicanes*, or rather *Metl* and *Maguei*, which is the *Aloe Americana*, set forth in the second Classis of this Worke, of whose leaves they made use to write or engrave what Records they would keepe, or what else they thought good. *Clusius* also maketh mention in his first Booke of Exotickes, and fourth Chapter, of two sorts of barkes of trees fit to write on: the one white and like unto the thinnest parchment which was gotten in *Iava*, by those that returned home with Sir *Francis Drake*, in his long voyage over the world, which by tryall was found fit to write on. And as he saith it might be was taken from that tree that *Antonius Pigafetta* maketh mention of in his journall, that in the Island *Tidore*, the women cover their privy parts, with a certaine cloath made of the barke of a tree in this manner: after it hath beene steeped so long in water that it is growne soft, they beate it with woodden mallets unto what length and breadth they please, making it so thinne as silke, having the crosse veines running through it: And it may as likely be such as the *Chineses* make their paper, some Bookes of herbes being brought into the Low Countries as *Clusius* saith, having both the figures of the herbes in them, and the descriptions, and vertues also peradventure, for they had *Chineses* Characters on the sides of the figures. The other barke of the tree was not white, but somewhat reddish, but of so smooth and fine a polished surface, as no paper could be smoother and plainer, and was not thicke or grosse but without any difficulty might be parted into six leaves, each of them very well enduring to be written on with our ordinary incke, and yet not sinke any whit through it, which barke as he saith might have beene separated into more leaves if one would have been curious about them.

## CHAP. CXLVI.

*Palma pinus sive Conifera.* The Pine or Conebearing Palme tree.

THis strange kinde of tree being brought by certaine *English* Merchants, or Marriners, from the parts of *Guinea* where they traded, was of a wonderfull composure, for the toppe bough with the fruite thereon, was as it were mixed, of the nature of the Date, and Pine tree together, the wood being light and spongy, and wholly made of threds or haires, the outside or barke being like scales: it had about forty or fifty round yet somewhat flat branches, a foote long in the same manner scaly, or as it were set with hollow joynted cuppes or boxes, and from the joynts broke forth small cones like to those of the Cedar tree, set with thicke scales of a pollished shining brownish colour, the outer shell being of the thickenesse of the Indian Nut shell, containing within it a certaine kernell like unto a long Ackorne or Chesnut, of two inches long or lesse, very hard and not easie to be made into meale, yet serving the Natives instead of bread.

*Fructus squamosus Palmæ alteræ similis.* Another kinde of scaly fruite like the other Palme.

Another scaly fruite like hereunto was sent unto *Clusius*, but came a little after his death, which sheweth the stalke of the fruit divided into long fibers, the fruite also divided, whose inner substance betweene the outer shell and the inner kernell was blacke, the smaller end of which kernell lay next the bottome of the fruite, differing from those in the Cokar Nuts.

*Chameriphes peregrina Clusij.* The strange dwarfe Palme of *Clusius*.

This branch *Clusius* referreth to the kindes of Palmetos as thinking it to partake with them: it rose up saith he

he, with forty stalkes or more bigger and lesser, and longer or shorter then others, containing many appearances of flowers or fruites growing thereon, which were all rubbed off, onely the places where they stood, appearing and shewed as if they had beene all contained within a huske or covering, for the whole branch rose from a certaine thicke barke, made as it were of shards like unto that of the outer shell of the Cokar Nut, or like unto that huske that covereth the *Palmeto* head, which barke was of a yellowish colour, smooth both above and below, but the stalkes were of a brownish colour: this seemed to be plucked from some tree, but what or where is not expressed.

## CHAP. CXLVII.

*Gum Copal & Anime.* Of Gum *Copal*, and Gum *Anime*.

THese two Gummes are gathered in the West Indies, as *Hispaniola, &c.* being very like one unto another: the *Copal* is of a fine cleare translucent pure white gum in somewhat great peeces, and pretty sweete, although not so much as the *Anime* is, with this Gum the Indians used to perfume their sacrifices instead of Incense in their temples, and when the *Spaniards* first came among them, they perfumed them therewith: it is hot in the second, and moist in the first degree, for it hath some watery parts therein, it resolveth swellings, and mollifieth hard tumours: *Gomara* maketh two sorts hereof, the one more rugged and soft then the other. But there hath been brought of late dayes, an oiely or liquid substance called *Oleum de copal Iva*, and is of two sorts, the one yellowish, and of a more thicke substance somewhat like unto that *Balsamum* that commeth from *Hispaniola*, the other whiter and more liquid, but of as sweete a sent as the former, both of them being excellent good for wounds &c. The *Anime* is also a whitish gumme, running out of great trees, and is not so cleare or pure white as the *Copal*, but more fatty like unto *Thus* or *Olibanum*, yet in greater peeces then *Olibanum* and being broken is somewhat yellowish, and of a most sweete and pleasant sent being set on burning or cast on quicke coales, and is soone consumed. There is another Gum *Anime* of *Ethiopia*, bordering on *Africa*, which is called *Orientale*, to distinguish it from this West Gum, and is both clearer, whiter, and in greater peeces then this, and is so like unto white Ambar, that divers have taken it to be melted Ambar, and thereof have made beads, and bracelets, &c. the tree from whence it commeth is great, having leaves like Mirtles: but I have here before shewed you the true originall of Ambar, even to be a *Bitumen*, which hath his fountaines in the *Germane* Sea, and becommeth hard, after it hath beene a while in the aire: Of this Orientall *Anime* also, I have shewed you the opinion of divers, both in the Chapter of *Lacca* and *Mirrha*, first that there is three sorts thereof, brought from *Guiney, &c.* by the *Portugals* and others, whereof that which is white is taken by *Garbias*, *Amatus Lusitanicus* and others, to be the true *Cancamum* of *Dioscorides*, and called *Animum* by the *Portugals*, serving for perfumes and censings: Another sort which is browne is taken by divers to be the *Myrrha Aminnæa* of *Dioscorides*, as is before said: The third sort is dry, of a pale colour, and is easily broken like Rossin. The West Gum *Anime*, is of much use in the defluctions of rheume from the head, and other diseases of the head, rising from a cold cause, the head ache also and megrime, and where there is want of sleepe to burne it, on a few quicke coales and aire ones head and their night cap with the smoke, which warmeth and comforteth the parts very much: and is herein very like unto *Thus*: it is used likewise in plasters to warme and strenghthen the cold and weake sinewes or any other part of the body afflicted with cold: it comforteth also a cold stomacke and helpeth to dissolve winde: it is also hot in the second and moist in the first degree.

## CHAP. CXLIX.

*Resinæ Americanæ quædam,* Certaine West Indie Rossins.

THere are divers other sorts of gums Rossins; and liquours brought both from the East, but especially from the West parts, some whereof by good experience have given much helpe they to those that have used them: many other more then they have beene brought, whereof wee have knowne no use or name, nor have made any tryall what effect they carry, and therefore to avoyd tediousnesse, and that this Worke being growne great, should not be overcharged with needlesse and unprofitable matter. I will onely in this Chapter shew you some of the chiefest that have beene either mentioned by others, or not set forth before now. The first is the *Resina Carthaginensis* set forth by *Monardus*, that was gathered by *Carthago nova* in *America*, and is a most cleare and most sweet liquid Rossin excelling either the Venice or the true Turpentine in the effects. For it is by often experience found to be singular good for wounds in the nerves and sinewes and the joynts or for old sores in the legges and feete: women by washing and preparing it in a convenient manner, doe use it on their faces to take away wrinckles, spots, &c. and to preserve their youth and beauty. Another sort is called also by *Monardus Resina Abiegua*, that is Firre tree liquid Rossin or Turpentine and is gathered from great wilde trees that can neither be said to be Firre or Cypresse, being taller then Pine trees, and straight, growing up like the Cypresse: towards the toppe of these trees grow certaine bladders or skinnes some greater and others smaller, which being broken this admirable liquour droppeth forth, which the Indians carefully doe gather into shells, but with a great deale of labour and trouble, and but a little in a great time. The use hereof is as effectuall as *Balsamum*, for all the causes for which *Balsamum* is used, for it excellently healeth all sorts of wounds, and easeth all paines and griefes rising from cold or flatulent matter: it is also singular good against the paines or winde in the stomacke and bowels, to take some in white wine. A third sort of liquid substance is called *Liquor Ambia* and came to him in the hollownesse of a cane or Reede, and was taken out of a spring or fountaine in the ground, farre from the sea, being thin and yellow like hony, and smelling like *Tacamahaca*, which was signified unto him to be of excellent vertues, especially in cold inveterate griefes, and aches in any part of the body, and taketh away the cold shivering fits of agues: it resolveth also all kindes of hard tumours, and performeth whatsoever either *Caranba* or *Tacamahacca* can doe: it is of so sticking and cleaving a substance, that it will not be pulled from the place whereon it is set, untill by time the vertue is spent and it growne dry. *Gum Colliman* or *Caramam*, is a kinde of blacke gum almost as blacke as pitch, that Sir *Walter Raleigh* first brought from *Guiana*, and those parts, and brought it also first into use for a cold moist and rheumaticke braine, and giddinesse thereof, and for defluxions of humours, as aches in the joynts or other parts, into the shoulders or other parts of the body, or for windinesse in them running from place to place, eyther by it selfe or sometimes mixed with *Caranba*: Of it selfe it is very hard, and smelleth sweete, but being distilled is much sweeter, especially the last part, that commeth forth after the two first stinking oyles, and is used by some perfumers as an excellent perfume.

*Resina Carthaginensis.*

*Resina Abiegua Indica.*

*Liquor Anbia.*

fume. It is good also for resolutions, or as some call it the dead palsie, and for the paines of the mother, and the lower part of womens backes, which must be spread upon leather as a plaister and laid thereon, and not taken away till it fall of it selfe: it is also singular good to ease the paines of the gout, and of excellent vertue in the cure of wounds: all these properties have beene found certaine by good experience.

*Barratta*, is a most soveraigne *Balsamum* farre excelling all others yet knowne, which by true experience is found to be of especiall operation in the cure of greene wounds, and being burned upon coales is a most sweet perfume.

And thus to finish this whole Worke and bring it to a period, let me onely shew you some of those things not spoken off before in this volume, which have beene made knowne to us to grow in our severall plantations of *Virginia*, the *Barmudas*, *New England*, or elsewhere among our owne peoples habitations: and first,

The poysoned weed is like our *English* Ivy.

The purging Beane is a kinde of Woodbind, running on trees neere the Sea side.

The Mancinell tree beareth a small apple like fruite, sweete in smell, but poyson to eate.

The Guane tree beareth a fruite as bigge as a Peate, and good to eate.

They have also Apple trees differing from ours.

Cherryes likewise as bigge as Damsons, and yellow Plummes divers from ours.

There is a bush like unto a Bramble that hath long yellow fruite within a hard shell.

Another tree they have that groweth great like a Pine tree that beareth fruite as great as a Musko Melon, is alwayes greene, and hath both blossomes, greene fruite, and ripe, all at a time.

Wilde Figge trees likewise they have, wherewith they feede their swine.

Then have they small red berryes which they call red Pepper.

Goodly great trees which they call Cedar, because the wood is red like Cedar, but the berryes are small like unto Iuniper berryes.

Fusticke trees, which give a yellow colour fit for Dyers,

A great tree with whose leaves they make Mustard.

A kinde of roote which they tooke to be *Sarsa parilla*, but is not, although somewhat like it, being hard and wooddy, and hath no use that we know.

*Mucca* nuts grow close to the ground like unto Hazell Nuts.

*Penimaw* is a kinde of silke grasse.

*Weghsacan*, with the roote they cure their hurts and diseases.

*Messaminus* are Grapes as great as Cherries, but with little juyce in them.

*Rawcomens* are like to our Gooseberryes.

*Ocoughtawmins*, are berries like unto Capers.

*Checinkamins* like to Chesnuts.

*Tockahough* is the Cassada roote whereof they make bread.

*Pappaw* is a fruite as bigge as an Apple, of an Orenge colour, and good to eate.

And now unto God Almighty *Triuno*, and *Vno in Trinitate*, who I hope hath beene at the beginning of this Worke, and holpen me through all the passages thereof, notwithstanding the *multa discrimina rerum mortalium*, whereof I have felt my part, to bring it to the end, for the benefit of others (who that they may make good use thereof, and not pervert it to any sinister course, is my earnest desire) be given all the praise, honour, and glory, for I am but (like the Bee, that workes out waxe and hony for others, not his owne good:) his instrument to accomplish it, receiving all from Him. *Amen.*

---

*FINIS.*

---

time. It is good also for relaxations, or as some call it the dead palsie, and for the pains of the mother, and the lower part of women bodies, which must be spread upon leather as a plaister and laid thereon, and so taken away till it fall of it selfe: it is also singular good to cale the pains of the gout, and of excellent vertue in the cure of wounds: all these properties have been found certaine by good experience.

*Balsamum*, is a most soveraigne *Balsamum* far exceeling all others yet known, which by true experience is found to be of especiall operation in the cure of greene wounds, and being burned upon coales is a most sweet perfume.

And thus to finish this whole Worke and bring it to a period, let me only shew some of those things not spoken of before in this volume, which have been made knowne to us to grow in our severall plantations of *Virginia*, the *Bermudas*, *New England*, or elsewhere among our owne peoples habitations and limits.

The poyisoned weed is like our *English* Ivy.

The pinning Beane is a kinde of Woodbind, running on trees neere the sea side.

The Mancinell tree beareth a small apple like fruite, weere in small, but poyson to eate.

The Guaue tree beareth a fruite as bigge as a Peare, and good to eate.

They have also Apple trees differing from ours.

Cherryes likewise as bigge as Damsons, and yellow Plumes differe from ours.

There is a bush like unto a Bramble that hath long yellow fruite within and dull.

Another tree they have that groweth great like a Pine tree that beareth fruite as great as a Muske Melon, always greene, and hath both blossomes, greene fruite, and ripe, all at a time.

Wilde figge trees likewise they have, whereunto they feede their swine.

Then have they small red berryes which they call red Pepper.

Goodly great trees which they call Cedar, because the wood is red like Cedar, but the berryes are small like unto pimpet berryes.

Pitch trees, which give a yellow colour fit for Dyers.

A great tree with wipe leaves they make Mullard.

A kinde of roote which they holde to be *Sarsaparilla*, but is not, although somewhat like it, being hard and woodly, and hath no ute that we know.

*Mulberries* grow close to the ground like unto Hazell Nuts.

*Tuna* is a kinde of wilde grape.

*Pumpkins*, with the roote they cure their burns and blaines.

*Mallowes* are Grapes as great as Cherries, but with little juyce in them.

*Rocomoco* are like to our Goosberryes.

*Cocoplumes*, are berries like unto Capers.

*Sacatamins* like to Chestnuts.

*Tockahoughs* is the Cassada roote whereof they make bread.

*Pappaw* is a fruite as bigge as an Apple, of an Orenge colour, and good to eate.

And now unto God Almighty *Triune*, and *Alpha* Twinnate, who I hope hath been at the beginning of this Worke, and holpen me through all the passages thereof, notwithstanding the many aduersaries whereof I have felt my part, to bringe it to the end, for the benefit of others (who that they may make good use thereof, and not pervert it to any finister end, I may earnestly desire) be given all the praise, honour, and glory. For I am but (like the Bee, that worker our wax and honey for others, not for its owne good) his instrument to accomplish it, receiving all from him.

*Amen.*

# THEATRO BOTANICO APPENDIX.

## An Appendix to the Theater of Plants, or Addition of those things have beene overslipt, mistaken, or to be amended in the Worke Precedent, to be referred as the number of *the Pages declare.*

Where observe that p. standeth for Page.

15. *Hyssopus Græcorum* so called by *Alpinus*, is that fifteenth sort in page the third, there called *Hissopus foliis Origani.* Round leafed Hysope.

6. *Thymbra Legitima Alpino.* The true Savory by *Alpinus.* Page. 5.

6. *Thymbra Legitima Alpino.* The true Savory by *Alpinus.*

The differing forme and face that *Alpinus* giveth this small herbe from the former, hath made me insert it here to be referred to the other sorts, if so be it be another. It is very like unto the true Tyme as he saith, but hath smaller and slenderer branches, and Tyme like leaves, many being set on them by couples, but thinner and softer, and of an herby greene colour: the flowers are purple like Tyme and grow in spikes: it groweth lower then Tyme, smelleth very like it, and tasteth as sharpe as Tyme, when it is dryed.

10. *Marum*

10. *Marum Ægyptiorum Alpino.* The Egiptians *Marum* by *Alpinus* to be referred to p. 13.

10. *Marum Ægyptiorum Alpino.*
The *Egyptians Marum* by *Alpinus* without sent.

This plant saith *Alpinus* accounted a *Marum* with the *Egiptians* and growing among rubbish and in dry places doth somewhat resemble a wild Clary in the leaves and growing, being voyd of taste or savour, especially the lowest, yet those that rise up with the stalke and flowers, are strong and not unpleasant, the leaves thereon being of a cubits height are white and hoary, and the flowers like those of Clary, the seedis small and round like Cabbage seed. They use to lay it among their garments, and Physically to expell winde powerfully, and to abate swellings.

5. *Origanum Indicum.* Indian Organy, or bastard Marjerome.

*Prosper Alpinus* in his Booke of *Egiptian* plants setteth forth one, he saith is there called *Zatarendi*, and decscribeth it to grow slowly with sundry branched stalkes and almost round thicke whitish leaves on them, full of sap or juyce, and very sweet, bearing neither flower nor fruite: they use it in their meates as others doe *Origanum*: thus much *Alpinus*. But *Vesslingius* taking upon him to correct and amend him saith, that the plant called *Satarhendi* by them is this plant (whose figure I here give you from him, and as he saith did spring with *Signior Coutarini* of *Venice*, if there be not some fallacy or mistake in the matter, for besides that *Alpinus* figure hath little similitude unto this, he saith, who it is likely observed it long by saying it grew slowly, he observed in all the time of his abode in *Egypt* that it bore nothing: but as soone as it came into *Contarinis* hands, it bore according as other sorts of *Origanum* both flowers and fruite yet larger. I put this but as a doubt in thē matter) and describeth it in this manner. This dainty plant riseth up to a footes height, with straight stalkes and soft tender Marjerome like leaves, upon them, covered with a whitish downe, or woull, being almost round but pointed at the ends, with sundry pale coloured veines in them: It beareth many white flowers at the tops of the stalkes, bowing their round heads a little, which are made of many small leaves set together. It is somewhat aromaticall in taste with some pleasing acrymony, and a little astringent withall, but exceedeth in sweetnes that of *Candy*.

2. *Origanum Onitis Matthioli.* White Organy of Greece. p. 15.

5. *Origanum Iudicum.* Another Indian Organy, or bastard Marjerome, p. 15.

10. *Polium Gnaphaloides.*
The hoary *Poley* mountaine.

This kind of *Poley* mountaine is wholly very hoary white all over, and having ſmall leaves like ſmall Myrtle leaves, a little dented about the edges, ſo thicke ſet on the lower crooked ſtemme, that they cover it, from whence arife divers other ſtalkes or branches, thinly ſet with the like leaves, and at the toppe of each of them a round head or umbell, upon a long bare ſtalke, conſiſting of divers yellow flowers, ſtanding in their ſmall cups, which growing ripe are turned into downe, and with the yellowiſh ſmall ſeed is carryed away with the winde: the roote is ſmall, ſlender, and long. *Alpinus* only maketh mention hereof *lib. de plantis exoticis.*

13. *Origanum fiſtuloſum Cornuto ſed potius Mentaſtrum fiſtuloſum Americanum.* A wild Mint of *America.*

The roote of this plant is wholly compoſed of long and ſmall fibres, which ſhooteth forth ſundry ſquare hairy ſtalkes halfe a yard high, ſet with two long and ſomewhat broad leaves at the joynts, ſomewhat reſembling thoſe of the Willow herbe: at the joynts come forth alſo divers branches with ſuch like leaves thereon, but leſſer up to the tops, where ſtand ten or twelve ſmal leaves in compaſſe, under the round head, compoſed of a number of pale reddiſh purple flowers, reſembling the head of a Scalion, each flower being long and hollow, biforked at the end, with two or three threds tipt with purple: in the middle of this round head ſhooteth forth ſometimes ſuch another round head of flowers, with leaves under them: the whole plant both ſtalke and leaves are covered with an hoary downe, and ſmelleth like Savory but taſteth ſharpe and fiery like Arſmart, yet the roote hath no taſte at all.

10. *Polium Gnaphaloides.*
Hoary Poley mountaine. p. 25.

13. *Origanum fiſtuloſum Cornuto, ſed potius Mentaſtrum fiſtuloſum Americanum.* A wild Mint of *America.* p. 34.

2. *Stœchas flore albo.*
White flowred Caſſidony. p. 67.

*Scordium spinosum odoratum.* Thorny sweete Scordium, or Water Germander. p. 110.

*Scordium spinosum odoratum.*

Thorny sweet *Scordium*, or Water Germander.

This annuall *Scordium* riseth up with square soft and hairy stalkes full of joynts or branches, which are fatty or clammy, whereat grow sometimes two, but at the greater joynts three leaves, which are variously formed, the lowest being largest, are dented or cut on the edges, like unto the ordinary or Water Germander, but still up higher the smaller and lesse dented, at the joynts of the branches grow many times long thornes, but alwayes end in a small long soft pricke or thorne, and at the leaves also come forth small Germanderlike flowers, but whitish, with three small threds within them: in the huskes that contained the flowers, being falne rise fowre small seeds which must be sowne every yeare: the roote is very long and fibrous, and perishing after seed time: the whole plant smelleth almost as sweet as *Bassill*, and was gathered upon some of the dry, barren and sandy mountaines in *Spaine*, and mentioned onely by *Cornutus* in his *Canada* relations.

Having another figure of this *Valerian* by me, differing in some things from the former, I thought good to exhibit it likewise unto you, that you may see how the alteration of climates causeth such formall diversities as are here perceived in rootes, leaves, and flowers.

18, 19. *Aster Americanus praecocior & serotinus latifolius & angustifolius.* Two sorts of Virginia Starreworts. p. 132

2. *Nardus montana Cretica.* Mountaine Nardus of *Candy*. p. 120.

2. *Scammo-*

2. *Scammonea macrorhyzos Cretica.*
Long rooted Scammony of *Candy*. p.164.

4. *Laurus sylvestris Cretica Alpini.*
The shrubby wild Bay of *Candy*. p.207.

To the end of the 25. Chapter of the second Classis, page 216. adde these words. But *Petrus Castellus* hath published a Tractate Printed at *Rome* 1612. in quarto, or as he calleth it an Epistle to *Iohanes Menelphus*, and *Aetius Cletus*, wherein he contesteth, that the *Helleborus* simply so called, as well in the Workes of *Hippocrates*, as other Authours entreating thereof, is to be understood of the white kinde, wherewith both the mad daughters of *Prætus* King of the *Argives* were cured, as also *Hercules* madnesse by the *Anticyrean* medicines (whose seed being like unto *Cnicus* was called *Sesamoides*) whose assertions I am sure are quite contrary to *Dioscorides*, that directly appropriateth the cure of *Prætus* daughters unto the blacke Ellebore, and therefore called also *Melampodium*, because *Melampus* the Goat-heard plaid the Physition therein.

3. *Acacalis Camerario Bollonio & alijs.* A *Syrian* plant like unto the Carob tree.

Being omitted in page 236. where it was entended to be set forth, that it be not utterly left out, accept it in this place. *Paludanus* saith *Bauhinus*, in his returne from his *Egiptian, Syrian, &c.* peregrination *Anno* 1579. brought some seedes of a *Syrian* plant, called there *Kismisen*, which being sowne brought forth round leaves, which he doubted was the *Acacalis* of *Dioscorides*. *Camerarius* also saith that he (as it is likely having received of the same seeds from *Paludanus*,) sowed some seed that was eight yeares old, sent him by the name of *Acacalis*, and called in the *Syriack* tongue *Kismisen*, and *Sisime*, from whence rose a tender plant, somewhat like unto the Carob tree, upon the first springing of it, having gained that yeare onely foure round leaves, set by couples, each opposite to other on the middle rib, whose stalke was somewhat hairy: This perished also at the beginning of Autumne, so that no more can be said thereof, but that the seed was somewhat broad and round at the one end, and pointed at the other. But although this bore the name of *Acacalis*, yet did it not answer to *Dioscorides* Text, (or *Ægineta* that transcribed it from him) that saith it is the fruite of an *Egiptian* plant, that is somewhat like unto Tamariske. *Cordus* commenting on *Dioscorides*, saith it was not knowne in his time, unlesse some would referre it to the *Elmblick* or *Bellirick Myrobolanes*, which is as farre from truth, as an Oake from an Apple. *Bellonius* also remembreth it, but giveth no description of it: So that neither being perfectly described by *Dioscorides*, nor certainely knowne of our Modernes, I can say no more thereof.

2. *Myrobolani Chebuli ut fertur Icon vera.*
A true figure of the purple Myrobalane or purging Indian Plumme.

*Vestingius* in his survay of *Alpinus* his *Egiptian* plants saith, that he often saw in the Orchard of a certaine chiefe Turke, a tree growing, which the keeper therof called *Dileg el chabul*, growing to be as bigge as a Plume tree, with a smooth pale coloured barke, the wood being whitish and somewhat sweet, the branches spread fairely and thicke, bending easily and hardly breaking, armed with sharpe long thornes: the leaves are set by couples together on a short footestalke, being somewhat long with the roundnesse, and a little round pointed (nothing like unto Peach leaves, as is formerly set downe) the lower ones being larger then those upward on the same branch: and without any dent on the edge. The fruite is of a reasonable greatnesse, bigge in the middle, and small at both ends, and of a darke or blackish red colour, and somewhat sapide. They use to preserve them, and so impart them to those of the greatest ranke, and have a purging quality in them.

2. *Myrobolani Chebuli ut fertur Icon vera.*
A branch of the true Chebull Myrobolane, or purple purging Indian Plume as it is thought, to be referred to p.246.

8. *Rubia sylvestris argentea Cretica.*
Silver-like wilde Madder of *Candy*.

This small *Candy* white Madder, from a small long slender roote shooteth forth divers stalkes, not halfe a foote long, with sundry small, long, soft and silver coloured leaves set by spaces, some times but two, other whiles foure at a space, and with them upwards to the toppe, small yellowish flowers, it is without any other taste then a little astringent, and is said to be profitable for fluxes in man or woman.

8. *Rubra sylvestris argentea Cretica.*
Silver like wild Madder of *Candy*. p 277.

*Capnos fabacea radice.*
*Bconkens Holatortel*, or small round rooted Fumiterry. p.288.

Page 380, Line the sixteenth, put out *Panaces Carpimon sive racemosum Canadense*, but why *Panax* being no wound herbe, I see no cause, unlesse it be for want of a better name, put out as I said all this, because it pertaineth to another place.

Page 380. Line the sixteenth, put out those three last lines in the *Names*, and instead of them put *Aconitum bacciniberis & rubris*: but I thinke I have more truely referred it to the *Christophoriana*. In the *Vertues* likewise put out the *Panaces Carpinon*, and all that followeth, and in the place thereof set these lines. *Cornutus* saith, they gave it the name of *Aconitum*, rather from the likenesse unto an Aconite then from any deliteriall quality they knew to be in it, and supposeth that the white berries should rather portend good then harme.

Page 387. Lines part of the 18. 19 and part of the 20. are to be strucke out, not being intended for that place, as may plainely be discerned by the relation. And in the stead thereof read these lines: The fourth is called by *Clusius Apocynum Syriacum Palestinum, & forte Ægyptium*, because he referreth it to the *Beidelsar* of *Alpinus* in his Booke of *Egiptian* plants, and to the *Ossar frutex* of *Honorius Bellus* in his third Epistle to him, saying withall, that Doctor *Christopher Weixius*, gave him the dryed branch, which he set forth, and that as he told him he gathered it neere the River *Iordan*, in *Palestina* where it grew, and the people there called it *Beidsar*: this is *Clusius* his relation and judgement thereof: I have said somewhat hereof in my former Booke, page 444. But I would to explaine it the better, adde somewhat more thereunto. First that it is not probable to me that this plant which *Clusius* setteth forth (and is without all question the very same that rose with me from the seed was brought out of *New England* upon the first discovery thereof, both stalkes, leaves, and flowers, agreeing so exactly thereunto, and both forme and colour of the flowers answering it in every point, onely the pods white seed answereth not unto this, which I doubt therefore is but mistaken) should be found naturall to those parts, seeing as I said it is naturall to *Virginia*, or *New England*, and especially that the name *Beidsar* should be given to it, which is most probable belongeth to that of *Alpinus*, and *Bellus*, which is quite a differing plant from this as I shewed in my former Booke, both from the growing hereof, which dyeth downe every yeare, and from the milke it giveth, which is not causticke like the Ossar, and in the rootes which are running under ground, which the other doth not. And thirdly, they say that the *Ossar* or *Beidelsar* beareth yellow flowers, and not expressed to grow in clusters as this doth; and Lastly, that the pods of this *Apocynum* are crooked, according to the forme expressed in the figure, when as those of *Ossar* are round like Testicles, and those that *Clusius* setteth forth are not crooked like unto these. *Bauhinus* in following *Clusius*, sheweth that he never saw the plant, and therefore taketh it for graunted whatsoever he said, or *Weixius* informed him, when as by this that I have here delivered it is probable *Weixius* was mistaken, and that hath caused all these errours: as also that of *Bauhinus*, that would make it a kinde of Docke, calling it *Lapathum Ægyptiacum lactescens siliqua Asclepiadis*, which hath so little correspondence with reason and judgement, that I wonder that so famous an Herbarist as *Bauhinus* was, should relye upon anothers foolish opinion in the denomination thereof, and so divulge it to the world, whereof I have formerly said something: The fifth is remembred by *Cornutus*, among his *Canada* plants.

*Ranunculus sylvarum sive Anemone sylvestris flore pleno albo.* The double white wilde Anemone to be inserted in p. 325.

*6. Pseudopacynum Virginianum, alijs Gelseminum Americanum maximum flore phœniceu.* The great Orrenge coloured *Virginia* Iasmine. to be inserted p. 385.

Of *Phalangium* in p. 418. *The Vertues.*

Spiderwort is of especiall property against all venome and poysons, as well of animalls, the Scorpion Spider *Phalangium*, and other Serpents, as of herbes and evill ayres or other quality whatsoever: it is held also to be preservative against infection, to continue the taking of the whole herbe, with the rootes either the poulter in wine or the decoction for a time, or to be tunned up with some *Angelica*, Goates Rue, and *Zedoaria*: it is singular good also against the winde and chollicke, to ease the tormenting paines thereof, and to avoid urine being stopped, or the paines of the stone.

*Radix Contrayervæ Hispanorum ut a Baptista Cortesio exhibitur.*
The roote of the *Spanish Contrayerva*, as *Cortesius* setteth it forth. to be referred to p. 421.

*6. Polygonum Serpillifolio Lobelij.*
*Lobels* Knotgrasse with Mother of Time leaves. p. 446.

*1. Prunella vulgaris.*
Common Selfeheale. p. 526.

*5. Herminum sylvestris vulgare.*
Our ordinary wilde Clary, or *Oculus christi*. p. 552.

5. Gallium

5. *Gallium montanum Creticum.* Mountaine Candy Gillium. p.565.

16. *Sideritis Heraclea Dioscoridis, sive Sideritis marina Saluifolia nostra Donato.*
Another Sage leafed sea Iron wort.

The roote is of the bigneſſe of ones little finger, wrinckled and of a yellowiſh colour: the ſtalke is wooddy and ſquare, at the bottome whereof come forth leaves like unto Sage, but ſomewhat greener, the leaves that grow upwards upon the ſtalke, are like unto the *Candy* Horehound, round about the tops of the branches doe the flowers ſtand ſomewhat like unto Sage, ſet in certaine cups being of a whitiſh or yellowiſh aſh-colour. It healeth any wound or ſore, not ſuffering humours to flow thereto, and ſome *Arabians* ſay it ſtayeth womens courſes: the leaves chawed doe taſte like Maſtick. There is another hebre growing in the ſame Iſle of *Lio* of the *Venetians*, very like to this, but that the leaves are ſmaller, the ſtalke is ſlenderer, and the flowers that grow at the tops, are more like unto thoſe of the Common *Calamint*. *Altera.*

*Aſſyroidis Cretica major.*
Great Saint *Peters* wort of Candy. p.574.

16. *Sideritis Heraclea Dioſcoridis, ſive altera Sideritis Saluifolio:*
Sage leafed Sea Ironwort. p.588.

2. *Alyſſum.*

3. *Alyssum montanum Columnæ.*
Madwort of *Columna.* p.590.

3. *Hesperis Pannonica inodora.*
Vnsavoury Dames Violets of Hungary. p 628.

3. *Alsine major quæ & media quibusdam.*
Great Chickeweed, which with some is called a middle sort. p.760.

*Viola tricolor flore duplici.* Hearts ease with a double flower. to be referred to p.756.

Page.733. Line the ſixt, before the laſt, inſert theſe references left out by overſight: The fourth with both the ſorts thereof are mentioned by *Cluſius*, under his ſecond *Cotyledon* and the ſpecies thereof; The fifth is onely remembred by *Columna*, who calleth it *Semper vivum rubrum montanum gnaphaloides*, *Bauhinus* not making any mention thereof that I can find: The ſixt is the third *Cotyledon* of *Cluſius*.

The figure of *Alſine minor* is to be taken away, being the *Anagallis fœmina flore cæruleo*, unto whoſe family it ſhould have beene referred but was negligently thruſt in here inſtead of the *Alſine major & minor*.

*Hieracium montanum tomentoſum ſive lanoſum.*

A mountaine hoary and woolly Hawkeweed. to be inſerted in p. 779.

This woolly Hawkeweed (which I know not by what chance it was left out of its due place, and therefore here to be inſerted and not to be utterly neglected) riſeth up with ſundry ſoft hoary round ſtalkes about halfe a yard high, ſet at each joynt with one long, ſomewhat narrow and waved leafe, whitiſh alſo, ſoft and woolly, and pointed at the ends: the flowers are ſmall of a pale yellow colour, conſiſting of threds rather then leaves, ſundry of them ſet together at the tops of the branched ſtalkes, which in time turne into downe, which with the ſeed is carryed away with the winde: the roote is whitiſh and ſtringy, periſhing every yeare, and muſt be yearely ſowne, and if the yeare prove not kindly, that the ſeed may be gathered thereof (as oftentimes it ſo happeneth) you are to ſeeke new ſeed, or ſow the old if you have any. This came among *Boels* ſeed from *Spaine*, where it is likely he gathered it, and ſent both to Maſter *Coys* and my ſelfe onely, howſoever another prevents me in the declaration.

*Melo vulgaris.* The ordinary Melon. p. 772.

3. *Thlaſpi biſbutaeum villoſum flore calcari dorato.*
Spurre flowred Buckler Thlaſpi. p. 845.

1. *Thapſia quædam latiore folio.*
Another broader leafed Fennell Thapſia. p. 277.

*Libanotidis*

*Libanotidis Galeni petalon genuinum.*
A true figure of a branch of the Fennell leafed Francumſence. p.881.

*Selini ſive Apij dulcis petalon.* A leafe of the ſweet Selinum or Smallage p.926

*4. Paſtinaca Echinophora Apula.*
Prickly wild Carrots of Naples. p.901.

It may be a queſtion whether this *Selinum* be not of the ſame quality with the ſweete Fennell, and ſweete Cumin, &c. The ſweetneſſe onely cauſed by the heate of the climates which altereth in the colder.

Page 964. Line 15. All that firſt relation of *Cnicus alter* is to be blotted out, and the ſecond and third, is to be made the firſt and ſecond.

Having

Having the ſame figure of *Laſerpitium* by me, that *Alp nus* ſet forth, I could doe no leſſe then ſhew it you, that you may ſee the difference of that ſtalke of leaves formerly exhibited, taken lineally from the vive Plant, and that of Lite from this of *Alpinus*, whoſe flowers and ſeed, is yet hid in the Embryon.

2. *L ſerpitium Alpino.*
*Alpinus* his Laſer wort. p.937.

Page 1086. Inſert this. 10. *Aſtragollo ſimilis palmata puſilla planta Lobelij.*
*Lobels French* ſmall Milke Vetch like plant.

This ſmall plant ſaith *Lobel*, he gathered on ſome of the hils of *Province* in *France*, having long wooddy rootes, covered with a thicke barke thereon, foulding one within another, and thickeſt at the head, from whence ſprung many ſtalkes that are hard, and but two or three inches long, whereon are ſet ſundry winged hoary ſmall hard leaves, like unto thoſe of Lentils, the milke Vetch or the Goates Thorne: at whoſe tops ſtand tufts of yellowiſh or whitiſh flowers, like unto thoſe of Birds foote, the plant is of a drying harſh taſte.

*Carlinæ capitulum clauſum.* The cloſed head of the Carline Thiſtle. p.963.

This

3. *Scolymus Theophrasti sive Eryngium luteum Monspeliensium.* The Golden Thistle. p. 572.

This true figure of the golden Thistle was I know not by what chance left out, and a false one put in the place, let this therefore supply the others defect.

3. *Rubus montanus odoratus.* Sweete mountaine Bramble or Raspis. p. 1013.

4. *Filix saxatilis crispa.* Small curled stone Ferne. p. 1044.

5. *Lathyrus arbensis radicibus tuberosis.* A differing sort of Earth nuts.

This sort differeth chiefly from this former fifth in having all the leaves onely set by couples, whereas the former hath more, and the ends of the pods are more twined. This is *Thalius* his *Astragalus arvensis.* p. 1062.

14. *Trifolium corniculatum Creticum flore luteo.* Horned Trefoile of *Candy* with yellow flowers.

This other horned Trefoile that came from *Candy*, where it is naturall, came to *Alpinus* as he saith, among other of their seeds, rising up with long and slender stalkes lying for the most part on the ground, having sundry small Trefoile leaves like a *Cytisus*, and somewhat broad forwards: The flowers grow at the ends of small stalkes, pease fashion, but small and yellow, with small round slender crooked pods succeeding, containing foure or five small yellow pease, which are eaten by the Natives even as the first sorts, yet is it not the same, for the pods hereof are slender and round although crooked, when as the other are flat and bigger. *Alpinus* onely hath made mention hereof, and differeth also as he saith from the *Trifolium Italicum corniculatum*, which is our *Lotus corniculatus incanus*, and the twelfth sort here.

Because I gave you not the figure of this Asphodill in my former Booke, although I gave you there the description, I thought good to shew it you now and referre you for the description to my former Booke. Yet this may take place for the present here, and accompany the greater Bastard kindes in page 1218.

12. *Linum umbilicatum.* Strange wild white flowred Flaxe.

This strange kind of Flaxe but annuall, rising up with slender hoary greene stalkes, branched towards the tops, having sundry whitish or hoary greene soft long leaves, set singly on them, somewhat broader and thicker then the ordinary wilde sorts, and with every leafe usually a small white flower, made of fine round pointed leaves, with a few threds in the middle, after which commeth the seede, set in the same huske that bore the flower, being somewhat like in forme and posture unto those of Hounds tongue, but not rough.

*Page* 1369. Line the fifteenth, reade it. We have another whose chiefest difference, &c.

14. *Trifolium corniculatum Lusitanicum flore rubro, & Creticum flore luteo.* Horned Trefoile of *Portugall* with red flowers, and one of *Candy* with yellow flowers. p. 1103.

*Asphodelus minor albus.* The small white Asphodill. p. 1218.

12. *Linum umbilicatum.* Strange wild white flowred Flaxe. p. 1336

2. *Alnus hirsuta sive folio incano.* The hoary Aldar tree. p. 1409.

*Macer Græcorum.* The *Grecians Macer.* p. 1599.

*Nardo Gangitidi spuriæ Narbonensi similis planta Virginiana cum floribus.* A Virginia bastard Nardus with the tops of the flowers, to be rendred either to page 115 or to p. 1595. where it is mentioned and described.

*Folium Mamey.* A leafe of the West Indian Peach Plum. p. 1633.

Vnto the eleventh number in page. 122. adde this. We have lately attained another sort hereof, agreeing in most things therewith, but that the leaves are of a fainter or fresher greene colour, the flowers are white, and called usually *Ocimastrum Valerianthos album.*

FINIS.
